# Chapter 1

## Introduction

Combinatorial optimization deals with problems in which we want to search for an optimal object in a finite set. Typically the set has a concise representation, but the number of objects is large.

**Definition: Graph**

A graph  $G = (V, E)$  is a set of vertices/nodes  $V$  and a set of edges  $E$ . We define  $n = |V|$  and  $m = |E|$ .

**Definition: Subgraph**

$H = (W, F)$  of  $G = (V, E)$  where  $W \subseteq V$  and  $F \subseteq E$ .

**Definition: Spanning Subgraph**

$H$  is spanning if  $V(H) = V(G)$ .

**Definition: Path**

A sequence  $P = v_0, e_1, v_1, \dots, e_k, v_k$  where  $v_0, \dots, v_k \in V(G)$ ,  $e_1, \dots, e_k \in E(G)$ , and  $e_i = v_{i-1}v_i$ .

We call  $P$  a  $v_0v_1$ -path.  $P$  is called edge-simple if all  $e_i$  are distinct and simple if all  $v_i$  are distinct.

The length of  $P$  is the number of edges in  $P$ .

**Definition: Circuit/Cycle**

An edge-simple closed path.

**Definition: Connected**

A graph is connected if every pair of vertices is joined by a path.

**Definition: Cut Vertex**

A node  $v$  of a connected graph  $G$  where  $G - v$  is not connected.

**Definition: Forest**

A graph with no circuits.

**Definition: Tree**

A connected forest.

**Definition: Cut**

Let  $R \subseteq V$ , then

$$\delta(R) = \{vw : vw \in E, v \in R, w \notin R\}$$

**Definition:  $rs$ -Cut**

A cut for which  $r \in R, s \notin R$ .

# Part I

## Minimum Spanning Trees

# Chapter 2

## Minimum Spanning Trees

### 2.1 Problem

**Definition: Spanning Tree**

A subgraph  $T \subseteq G$  where  $V(T) = V(G)$ ,  $T$  is connected, and  $T$  is acyclic.

**Lemma**

An edge  $e = uv$  of  $G$  is an edge of a circuit of  $G$  if and only if there is a path in  $G \setminus e$  from  $u$  to  $v$ .

**Minimum Spanning Tree Problem (MST)**

Given a connected graph  $G$  and a real cost  $c_e$  for each  $e \in E$ , find a minimum cost spanning tree of  $G$ .

**Lemma**

A spanning connected subgraph of  $G$  is a spanning tree if and only if it has exactly  $n - 1$  edges.

### 2.2 Algorithm

**Theorem**

A graph  $G$  is connected if and only if there is no set  $A \subseteq V$  where  $\emptyset \neq A \neq V$  with  $\delta(A) = \emptyset$ .

---

**Algorithm 1** Kruskal's Algorithm for MST

---

```
1: sort  $E$  to  $\{e_1, \dots, e_m\}$  so that  $c_{e_1} \leq \dots \leq c_{e_m}$ 
2:  $H = (V, F)$ ,  $F = \emptyset$ 
3: for  $i = 1$  to  $m$  do
4:   if ends of  $e_i$  are in different components of  $H$  then
5:      $F \leftarrow F \cup \{e_i\}$ 
6: return  $H$ 
```

---

## 2.3 Linear Programming Relaxation

**Definition:**  $\kappa : E \rightarrow \mathbb{N}$

$\kappa(A)$

We can formulate the MST problem as an IP.

$$\begin{aligned} \min \quad & c^T x \\ \text{s.t.} \quad & x(A) \leq |V| - \kappa(A), \quad \forall A \subset E \\ & x(E) = |V| - 1 \\ & x_e \in \{0, 1\}, \quad \forall e \in E \end{aligned}$$

We can relax the integer program to get the following linear program.

**Definition: MST Linear Program**

$$\begin{aligned} \min \quad & c^T x \\ \text{s.t.} \quad & x(A) \leq |V| - \kappa(A), \quad \forall A \subset E \\ & x(E) = |V| - 1 \\ & x_e \geq 0, \quad \forall e \in E \end{aligned}$$

We replace the minimization with a maximization in the primal to write the dual.

**Definition: MST Dual Linear Program**

$$\begin{aligned} \min \quad & \sum_{A \subseteq E} (|V| - \kappa(A)) y_A \\ \text{s.t.} \quad & \sum_{A: e \in A} y_A \geq -c_e, \quad \forall e \in E \\ & y_A \geq 0, \quad \forall A \subset E \end{aligned}$$

**Theorem (Edmonds 1971)**

Let  $x^*$  be the characteristic vector of an MST with respect to costs  $c_e$ . Then  $x^*$  is an optimal solution of the linear program.

**Proof.** We show that  $x^*$  is optimal for the LP and  $x^*$  is the characteristic vector generated by Kruskal's algorithm.  $y_E$  is not required to be nonnegative.

Let  $e_1, \dots, e_m$  be the order in which Kruskal's algorithm considers the edges. Let  $R_i = \{e_1, \dots, e_i\}$  for  $1 \leq i \leq m$ . Let  $y^*$  be the dual solution. We denote  $y_A^* = 0$  unless  $A$  is one of the  $R_i$ ,  $y_{R_i}^* = c_{e_{i+1}} - c_{e_i}$  for  $1 \leq i \leq m-1$ , and  $y_{R_m}^* = -c_{e_m}$ . It follows from the ordering of the edges,  $y_A^* \geq 0$  for  $A \neq E$ . Now consider the first constraint, then where  $e = e_i$ , we have

$$\sum_{A: e \in A} y_A^* = \sum_{j=i}^m y_{R_j}^* = \sum_{j=i}^{m-1} (c_{e_{j+1}} - c_{e_j}) = -c_{e_i} = -c_e$$

All of the inequalities hold with equality. So the complementary slackness conditions ( $x_e^* > 0 \implies \sum_{A: e \in A} y_A^* = c_e$ ) are satisfied.

We want to show now that the second constraint also satisfies complementary slackness conditions ( $y_A^* > 0 \implies x(A) \leq |V| - \kappa(A)$ ). We know  $A = R_i$  for some  $i$ . If the primal constraint does not hold with equality for  $R_i$ , then there is some edge of  $R_i$  whose addition to  $E(T) \cap R_i$  would decrease the number of components of  $(V, E(T) \cap R_i)$ . But this edge would have ends in two different components of  $(V, E(T) \cap R_i)$ , and therefore would have been added to  $T$  by Kruskal's algorithm.

Therefore,  $x^*$  and  $y^*$  satisfy complementary slackness conditions. So,  $x^*$  is an optimal solution to the LP.  $\square$

# **Part II**

## **Network Flows**

# Chapter 3

## Maximum Flow

### 3.1 Problem

#### Definition: Net Flow/Excess

$$f_x(v) = x(\delta(\bar{v})) - x(\delta(v)) = \sum_{w \in V, wv \in E} x_{wv} - \sum_{w \in V, vw \in E} x_{vw}$$

#### Definition: $rs$ -Flow

A vector  $x$  that satisfies  $f_x(v) = 0$  for all  $v \in V$ .

#### Definition: Value of $rs$ -Flow

$$f_x(s)$$

#### Maximum Flow Problem

Given a digraph  $G = (V, E)$ , with source  $r$  and sink  $s$ , find an  $rs$ -flow of maximum value.

#### Proposition

There exists a family  $(P_1, \dots, P_k)$  of  $rs$ -dipaths such that  $|\{i : e \in P_i\}| \leq u_e$  for all  $e \in E$  if and only if there exists an integral feasible  $rs$ -flow of value  $k$ .

**Proof.** ( $\implies$ ) We have seen family of dipaths determines a corresponding flow.

( $\impliedby$ ) Let  $x$  be a flow. We assume that  $x$  is acyclic, that is, there is no dicircuit  $C$ , each of whose arcs  $e$  has  $x_e > 0$ . If a dicircuit does exist, we can decrease  $x_e$  by 1 on all arcs of  $C$ . The new  $x$  remains feasible of value  $k$ .

If  $k \geq 1$ , we can find an arc  $vs$  with  $x_{vs} \geq 1$ . Then, if  $v \neq r$ , it follows that there is an arc

$wv$  with  $x_{wv} \geq 1$  by the constraint  $f_x(v) = 0$ . If  $w \neq r$ , then the argument can be repeated producing distinct vertices, since  $x$  is acyclic, so we get a simple  $rs$ -dipath  $P_k$  on each arc  $e$  with  $x_e \geq 1$ . We can decrease  $x_e$  by 1 for each  $e \in P_k$ . The new  $x$  is an integral feasible flow of value  $k - 1$ , and the process is repeated.  $\square$

## 3.2 Maximum Flows and Minimum Cuts

### Definition: Maximum Flow Linear Program

$$\begin{aligned} \max \quad & f_x(s) \\ \text{s.t.} \quad & f_x(v) = 0, \forall v \in V \setminus \{r, s\} \\ & 0 \leq x_e \leq u_e, \forall e \in E \end{aligned}$$

### Definition: Path Flow

A vector  $x \in \mathbb{R}^E$  such that for some  $rs$ -dipath  $P$  and some  $\alpha \in \mathbb{R}$ ,  $x_e = \alpha$  for each  $e \in P$  and  $x_e = 0$  for every other arc of  $G$ .

### Definition: Circuit Flow

A vector  $x \in \mathbb{R}^E$  such that for some  $rs$ -dicircuit  $C$  and some  $\alpha \in \mathbb{R}$ ,  $x_e = \alpha$  for each  $e \in C$  and  $x_e = 0$  for every other arc of  $G$ .

### Proposition

Every  $rs$ -flow of nonnegative value is the sum of at most  $m$  flows, each of which is a path flow or a circuit flow.

### Proposition

For any  $rs$ -cut  $\delta(R)$  and any  $rs$ -flow  $x$ , we have

$$f_x(s) = x(\delta(R)) - x(\delta(\bar{R}))$$

**Proof.** We add the equations  $f_x(v) = 0$  for all  $v \in \bar{R} \setminus \{s\}$  as well as the identity  $f_x(s) = f_x(s)$ . The right hand side sums to  $f_x(s)$ .

For any arc  $vw$  with  $v, w \in R$ ,  $x_{vw}$  occurs in none of the equations, so it does not occur in the sum. If  $v, w \in \bar{R}$ , then  $x_{vw}$  occurs in the equation for  $v$  with a coefficient of  $-1$ , and in the equation for  $w$  with a coefficient of  $+1$ , so it has a coefficient of  $0$  in the sum. If  $v \in R, w \notin R$ , then  $x_{vw}$  occurs in the equation for  $w$  with a coefficient of  $1$ , and so has coefficient  $1$  in the sum. If  $v \notin R, w \in R$ , then  $x_{vw}$  occurs in the sum with a coefficient of  $-1$ . So, the left hand side sums to  $x(\delta(R)) - x(\delta(\bar{R}))$ , as required.  $\square$

### Corollary

For any feasible  $rs$ -flow  $x$  and any  $rs$ -cut  $\delta(R)$ ,

$$f_x(s) \leq u(\delta(R))$$

**Proof.** Using previous proposition, since  $x(\delta(R)) \leq u(\delta(R))$  and  $x(\delta(\bar{R})) \geq 0$ .  $\square$

### Definition: Incrementing Path

A path is  $x$ -incrementing if every forward arc  $e$  has  $x_e < u_e$  and every reverse arc  $e$  has  $x_e > 0$ .

### Definition: Augmenting Path

An  $rs$ -path that is  $x$ -incrementing.

### Theorem Maximum-Flow Minimum-Cut

If there is a maximum  $rs$ -flow, then

$$\max\{f_x(s) : x \text{ is a feasible } rs\text{-flow}\} = \min\{u(\delta(R)) : \delta(R) \text{ is an } rs\text{-cut}\}$$

**Proof.** By previous corollary, we need only show that there exists a feasible flow  $x$  and a cut  $\delta(R)$  such that  $f_x(s) = u(\delta(R))$ . Let  $x$  be a flow of maximum value. Let  $R = \{v \in V : \text{there exists an } x\text{-incrementing } rv\text{-path}\}$ . Clearly  $r \in R$  and  $s \notin R$ , since there can be no  $x$ -augmenting path.

For every arc  $vw \in \delta(R)$ , we must have  $x_{vw} = u_{vw}$ , since otherwise adding  $vw$  to the  $x$ -incrementing  $rv$ -path would yield such a path to  $w$ , but  $w \notin R$ . Similar, for every arc  $vw \in \delta(\bar{R})$ , we have  $x_{vw} = 0$ . Then by proposition,  $f_x(s) = x(\delta(R)) - x(\delta(\bar{R})) = u(\delta(R))$ .  $\square$

### Theorem

A feasible flow  $x$  is maximum if and only if there is not  $x$ -augmenting path.

**Proof.** ( $\implies$ ) If  $x$  is maximum, there is no  $x$ -augmenting path.

( $\impliedby$ ) If there is no  $x$ -augmenting path, then the construction of the proof of Max-Flow Min-Cut yields a cut  $\delta(R)$  with  $f_x(s) = u(\delta(R))$ , so  $x$  is maximum, by corollary.  $\square$

### Theorem

If  $u$  is integral and there exists a maximum flow, then there exists a maximum flow that is integral.

**Proof.** Choose an integral flow  $x$  of maximum value. If there is an  $x$ -augmenting path, then since  $x$  and  $u$  are integral, the new flow can be chosen integral, contradicting the choice of  $x$ . Hence there is no  $x$ -augmenting path, so  $x$  is a maximum flow, by previous theorem.  $\square$

### Corollary

If  $x$  is a feasible  $rs$ -flow and  $\delta(R)$  is an  $rs$ -cut, then  $x$  is maximum and  $\delta(R)$  is minimum if and only if  $x_e = u_e$  for all  $e \in \delta(R)$  and  $x_e = 0$  for all  $e \in \delta(\bar{R})$ .

**Proof.** Combine Max-Flow Min-Cut theorem with the proof of corollary.  $\square$

## 3.3 Augmenting Path Algorithm

### Ford-Fulkerson Algorithm

- 1:  $x = 0$
- 2: **while** there is an  $x$ -augmenting path  $P$  **do**
- 3:    $\varepsilon_1 = \min(u_e - x_e : e \text{ forward in } P)$
- 4:    $\varepsilon_2 = \min(x_e : e \text{ reverse in } P)$
- 5:    $\varepsilon = \min(\varepsilon_1, \varepsilon_2)$    //  $x$ -width of  $P$
- 6:   **if**  $\varepsilon = \infty$  **then**
- 7:     no maximum flow
- 8: **return**  $x$  is maximum flow, set  $R$  of vertices reachable by an  $x$ -augmenting path from  $r$  is minimum cut

### Definition: Auxiliary Digraph

$G(x)$ , depending on  $G, u, x$ , where  $V(G(x)) = V$  and  $vw \in E(G(x))$  if and only if  $vw \in E$  and  $x_{vw} < u_{vw}$  or  $wv \in E$  and  $x_{wv} > 0$ .

$rs$ -dipaths in  $G(x)$  corresponding to  $x$ -augmenting paths in  $G$ . Each iteration of Ford-Fulkerson can be performed in  $O(m)$  time, using breadth-first search.

### Theorem

If  $u$  is integral and the maximum flow value is  $K < \infty$ , then the maximum flow algorithm terminates after at most  $K$  augmentations.

### 3.3.1 Shortest Augmenting Paths

#### Theorem (Dinitz 1970, Edmonds & Karp 1972)

If each augmentation of the augmenting path algorithm on a shortest augmenting path, then there are at most  $nm$  augmentations.

### Corollary

The augmenting path algorithm with breadth-first search solves the maximum flow problem in time  $O(nm^2)$ .

Let  $d_x(v, w)$  be the least length of a  $vw$ -dipath in  $G(x)$ .  $d_x(v, w) = \infty$  if no  $vw$ -dipath exists.

Consider a typical augmentation from flow  $x$  to flow  $x'$  determined by the augmenting path  $P$  having vertex-sequence  $v_0, \dots, v_k$ .

**Lemma**

For each  $v \in V$ ,  $d_{x'}(r, v) \geq d_x(r, v)$  and  $d_{x'}(v, s) \geq d_x(v, s)$ .

**Proof.** Suppose that there exists a vertex  $v$  such that  $d_{x'}(r, v) < d_x(r, v)$  and choose such  $v$  so that  $d_{x'}(r, v)$  is as small as possible. Clearly,  $d_{x'}(r, v) > 0$ . Let  $P'$  be a  $rv$ -dipath in  $G(x')$  of length  $d_{x'}(r, v)$  and let  $w$  be the second-last vertex of  $P'$ . Then

$$d_x(r, v) > d_{x'}(r, v) = d_{x'}(r, w) + 1 \geq d_x(r, w) + 1$$

It follows that  $wv$  is an arc of  $G(x')$ , but not of  $G(x)$ , otherwise  $d_x(r, v) \leq d_x(r, w) + 1$ , so  $w = v_i$  and  $v = v_{i-1}$  for some  $i$ . But, this implies that  $i - 1 > i + 1$ , a contradiction. The second statement is similar.  $\square$

**Definition:**  $\tilde{E}(x)$

$$\tilde{E}(x) = \{e \in E : e \text{ is an arc of a shortest } x\text{-augmenting path}\}$$

**Lemma**

If  $d_{x'}(r, s) = d_x(r, s)$ , then  $\tilde{E}(x') \subsetneq \tilde{E}(x)$ .

**Proof.** Let  $k = d_x(r, s)$  and suppose that  $e \in \tilde{E}(x')$ . Then  $e$  induces an arc  $vw$  of  $G(x')$  and  $d_{x'}(r, v) = i - 1$ ,  $d_{x'}(ws) = k - i$  for some  $i$ . Therefore,  $d_x(r, v) + d_x(w, s) \leq k - 1$  by previous lemma. Now suppose that  $e \notin \tilde{E}(x)$ , then  $x_e \neq x'_e$ , so  $e$  is an arc of  $P$ , a contradiction. This proves  $\tilde{E}(x') \subseteq \tilde{E}(x)$ .

There is an arc  $e$  of  $P$  such that  $e$  is forward and  $x'_e = u_e$  or  $e$  is reverse and  $x'_e = 0$ . Therefore, any  $x'$ -augmenting path using  $e$  must use it in the opposite direction from  $P$ , so its length, for some  $i$ , will be at least  $i + k - i + 1 + 1 = k + 23$ , so  $e \notin \tilde{E}(x')$ .  $\square$

**Proof.** (Dinitz, Edmonds, Karp) It follows from previous lemma that there can be at most  $m$  augmentations per stage. Since there are at most  $n - 1$  stages, there are at most  $nm$  augmentations in all.

## 3.4 Applications

### 3.4.1 Bipartite Matchings and Vertex Covers

#### Theorem (König)

For a bipartite graph  $G$ ,

$$\max\{|M| : M \text{ a matching}\} = \min\{|C| : C \text{ a cover}\}$$

### 3.4.2 Flow Feasibility

#### Flow Feasibility Problem

Given a digraph  $G$ ,  $u \in \mathbb{R}_+^E$ , and  $b \in \mathbb{R}^V$ , find, if possible,  $x \in \mathbb{R}^E$  such that

$$f_x(v) = b_v, \quad \forall v \in V$$

and

$$0 \leq x_e \leq u_e, \quad \forall e \in E$$

#### Theorem (Gale 1957)

There exists a solution to the flow feasibility problem if and only if  $b(V) = 0$  and for every  $A \subseteq V$ ,  $b(A) \leq u(\delta(\overline{A}))$ .

If  $b$  and  $u$  are integral, then there is an integral solution.

#### Corollary

Given a digraph  $G$  and  $b \in \mathbb{R}^V$ , there exists  $x \in \mathbb{R}^E$  with

$$f_x(v) = b_v, \quad \forall v \in V$$

$$x_e \geq 0, \quad \forall e \in E$$

if and only if  $b(V) = 0$  and for every  $A \subseteq V$  with  $\delta(\overline{A}) = \emptyset$ , we have  $b(A) \leq 0$ .

#### Definition: Circulation

A vector  $x \in \mathbb{R}^E$  with  $f_x(v) = 0$  for all  $v \in V$ .

#### Theorem (Hoffman's Circulation Theorem 1960)

Given a digraph  $G$ ,  $\ell \in (\mathbb{R} \cup \{-\infty\})^E$ , and  $u \in (\mathbb{R} \cup \{\infty\})^E$ , with  $\ell \leq u$ , there is a circulation  $x$  with  $\ell \leq x \leq u$  if and only if every  $A \subseteq V$  satisfies  $u(\delta(\overline{A})) \geq \ell(\delta(A))$ .

# Part III

## Matchings

# Chapter 4

## Matchings

**Definition: Matching**

A set  $M \subseteq E$  such that no vertex of  $G$  is incident with more than one edge in  $M$ .

**Definition:  $M$ -Covered**

A vertex  $v$  is covered by  $M$  if some edge of  $M$  is incident with  $v$ .

**Definition:  $M$ -Exposed**

A vertex  $v$  is exposed if  $v$  is not  $M$ -covered.

The number of vertices covered by  $M$  is  $2|M|$  and number of  $M$ -exposed vertices is  $|V| - 2|M|$ .

**Definition: Maximum Matching**

A matching of maximum cardinality, denoted by  $\nu(G)$ .

**Definition: Deficiency**

The minimum number of exposed vertices for any matching of  $G$ , denoted by  $\text{def}(G)$ .

Note  $\text{def}(G) = |V| - 2\nu(G)$ .

**Definition: Perfect Matching**

A matching that covers all vertices.

## 4.1 Alternating Paths

### Definition: $M$ -Alternating

A path  $P$  is  $M$ -alternating if its edges are alternately in and not in  $M$ .

### Definition: $M$ -Augmenting

An  $M$ -alternating path  $P$  is  $M$ -augmenting if the ends of  $P$  are distinct and are both  $M$ -exposed.

### Definition: Symmetric Difference

For sets  $S$  and  $T$ , let  $S \Delta T$  denote the symmetric difference, which is defined as

$$S \Delta T = (S \cup T) \setminus (S \cap T)$$

### Theorem (Augmenting Path Theorem of Matchings – Berge 1957)

A matching  $M$  in a graph  $G$  is maximum if and only if there is no  $M$ -augmenting path.

**Proof.** ( $\implies$ ) Suppose there exists an  $M$ -augmenting path  $P$  joining  $v$  and  $w$ . Then  $N = M \Delta E(P)$  is a matching that covers all vertices covered by  $M$ , plus  $v$  and  $w$ . So,  $M$  is not maximum.

( $\impliedby$ ) Conversely, suppose that  $M$  is not maximum and some other matching  $N$  satisfies  $|N| > |M|$ . Let  $J = N \Delta M$ . Each vertex of  $G$  is incident with at most two edges of  $J$ , so  $J$  is the edge set of some vertex disjoint paths and circuits of  $G$ . For each such path or circuit, the edges alternately belong to  $M$  or  $N$ . Therefore, all circuits are even and contain the same number of edges of  $M$  and  $N$ . Since  $|N| > |M|$ , there must be at least one path with more edges of  $N$  than  $M$ . This path is an  $M$ -augmenting path.  $\square$

## 4.2 Tutte-Berge Formula

### Definition: Vertex Cover

A set  $A$  of vertices such that every edge has at least one end in  $A$ .

Let  $A$  be a subset of the vertices which  $G - A$  has  $k$  components  $H_1, \dots, H_k$  having an odd number of vertices. Let  $M$  be a matching of  $G$ . For each  $i$ , either  $H_i$  has an  $M$ -exposed vertex or  $M$  contains an edge having just one end in  $V(H_i)$ . All such edges have their other ends in  $A$  and since  $M$  is a matching, all these ends must be distinct. Therefore, there can be at most  $|A|$  edges and so the number of  $M$ -exposed vertices is at least  $k - |A|$ .

**Definition:**  $\text{oc}(H)$

The number of odd components of a graph  $H$ .

Thus, for any  $A \subseteq V$ ,

$$\nu(G) \leq \frac{1}{2}(|V| - \text{oc}(G - A) + |A|)$$

If  $A$  is a cover of  $G$ , then there are  $|V| - |A|$  odd components of  $G - A$  (each is a single vertex), so the right hand side reduces to  $|A|$ . This bound is at least as strong as that provided by covers.

**Theorem (Tutte-Berge Formula)**

For a graph  $G = (V, E)$ , we have

$$\max\{|M| : M \text{ a matching}\} = \min\left\{\frac{1}{2}(|V| - \text{oc}(G - A) + |A|) : A \subseteq V\right\}$$

**Theorem (Tutte's Matching Theorem 1947)**

A graph  $G = (V, E)$  has a perfect matching if and only if for every  $A \subseteq V$ ,  $\text{oc}(G - A) \leq |A|$ .
