Part I

Introduction

Chapter 1

Introduction

Definition: Combinatorial Optimization

A subfield of mathematical optimization which involves searching for an optimal object in a finite collection of objects.

Typically, the collection has a concise representation, while the number of objects is large. Objects include graphs, networks, and matroids.

The main tool in combinatorial optimization is linear programming duality.

Chapter 2

Linear Programming

Definition: Linear Programming

The problem of finding a vector x that maximizes a given linear function $c^T x$, where x ranges over all vectors satisfying a given system $Ax \leq b$ of linear inequalities.

2.1 Farkas' Lemma

Lemma (Farkas' Lemma for Inequalities)

The system $Ax \leq b$ has a solution x if and only if there is no vector y satisfying $y \geq 0$, $y^T A = 0$, and $y^T b < 0$.

Proof. Suppose $Ax \leq b$ has a solution \bar{x} and suppose there exists a vector $\bar{y} \geq 0$ satisfying $\bar{y}^T A = 0$ and $\bar{y}^T b < 0$. Then we obtain the contradiction

$$0 > \bar{y}^T b \geq \bar{y}^T (A\bar{x}) = (\bar{y}^T A)\bar{x} = 0$$

Now suppose that $Ax \leq b$ has no solution. If A has only one column, then the result is easy. Otherwise, apply Fourier-Motzkin elimination to obtain a system $A'x' \leq b'$ with one less variable. Since $A'x' \leq b'$ also has no solution, we can assume by induction that there exists a vector $y' \geq 0$ satisfying $y'^T A' = 0$ and $y'^T b' < 0$. Now since each inequality in $A'x' \leq b'$ is the sum of positive multiples of inequalities in $Ax \leq b$, we can use y' to construct a vector y satisfying the conditions in the theorem. \square

Lemma (Farkas' Lemma)

The system $Ax = b$ has a nonnegative solution if and only if there is no vector y satisfying $y^T A \geq 0$ and $y^T b < 0$.

Proof. Define

$$A' = \begin{bmatrix} A \\ -A \\ -I \end{bmatrix}, b' = \begin{bmatrix} b \\ -b \\ 0 \end{bmatrix}$$

Then $Ax = b$ has a nonnegative solution x if and only if $A'x' \leq b'$ has a solution x' . Applying Farkas' Lemma for Inequalities to $A'x' \leq b'$ gives the result. \square

Corollary

Suppose the system $Ax \leq b$ has at least one solution. Then every solution x of $Ax \leq b$ satisfies $c^T x \leq \delta$ if and only if there exists a vector $y \geq 0$ such that $y^T A = c$ and $y^T b \leq \delta$.

2.2 Duality

Consider the LP:

$$\begin{array}{ll} \max & c^T x \\ \text{s.t.} & Ax \leq b \end{array}$$

and dual LP

$$\begin{array}{ll} \min & y^T b \\ \text{s.t.} & y^T A = c^T \\ & y \geq 0 \end{array}$$

Theorem (Weak Duality)

Let A be an $m \times n$ matrix, $b \in \mathbb{R}^m$, $c \in \mathbb{R}^n$. Suppose that \bar{x} is a feasible solution to $Ax \leq b, x \geq 0$ and \bar{y} is a feasible solution to $y^T A \geq c^T, y \geq 0$. Then

$$c^T \bar{x} \leq \bar{y}^T b$$

Proof.

$$c^T \bar{x} \leq (\bar{y}^T A) \bar{x} = \bar{y}^T (A \bar{x}) \leq \bar{y}^T b$$

\square

Theorem (Duality Theorem)

Let A be an $m \times n$ matrix, $b \in \mathbb{R}^m$, $c \in \mathbb{R}^n$, then

$$\max\{c^T x : Ax \leq b, x \geq 0\} = \min\{y^T b : y^T A \geq c^T, y \geq 0\}$$

provided that both sets are nonempty.

2.3 Complementary Slackness

Consider the LP and dual LP

$$\max\{c^T x : Ax \leq b, x \geq 0\} = \min\{y^T b : y^T A \geq c^T, y \geq 0\}$$

Definition: Complementary Slackness Conditions

Suppose \bar{x}, \bar{y} are feasible solutions to the primal and dual.

- If a component of $\bar{x} > 0$, then the corresponding inequality in $y^T A \geq c^T$ is satisfied by \bar{y} with equality, i.e.

$$(\bar{y}^T A - c^T)\bar{x} = 0$$

- If a component of $\bar{y} > 0$, then the corresponding inequality in $Ax \leq b$ is satisfied by \bar{x} with equality, i.e.

$$\bar{y}^T(b - A\bar{x}) = 0$$

Theorem (Complementary Slackness Theorem)

Let \bar{x} be a feasible solution of $\max\{c^T x : Ax \leq b, x \geq 0\}$ and let \bar{y} be a feasible solution of $\min\{y^T b : y^T A \geq c^T, y \geq 0\}$. Then the following are equivalent:

- \bar{x}, \bar{y} are optimal solutions.
- $c^T \bar{x} = \bar{y}^T b$
- The complementary slackness conditions hold.

Proof. ((a) \iff (b)) By Duality Theorem.

((b) \iff (c)) By Weak Duality, we have $c^T \bar{x} \leq \bar{y}^T A\bar{x} \leq \bar{y}^T b$. So,

$$\begin{aligned} c^T \bar{x} = \bar{y}^T b &\iff \bar{y}^T A\bar{x} = c^T \bar{x} \text{ and } \bar{y}^T b = \bar{y}^T A\bar{x} \\ &\iff (\bar{y}^T A - c^T)\bar{x} = 0 \text{ and } \bar{y}^T(b - A\bar{x}) = 0 \end{aligned}$$

□

Chapter 3

Graph Theory

Definition: Graph

A graph $G = (V, E)$ is a set of vertices/nodes V and a set of edges E . We define $n = |V|$ and $m = |E|$.

Definition: Digraph

A digraph $G = (V, E)$ is a set of vertices/nodes V and a set of edges E , sometimes called arcs, where each $e \in E$ has two ends, one called the head $h(e)$ and the other called the tail $t(e)$.

Definition: Forward Arc

In a path $v_0, e_1, v_1, \dots, e_k, v_k$, $e_i \in P$ is called forward if $t(e_i) = v_{i-1}$ and $h(e_i) = v_i$.

Definition: Backward Arc

In a path $v_0, e_1, v_1, \dots, e_k, v_k$, $e_i \in P$ is called backward if $t(e_i) = v_i$ and $h(e_i) = v_{i-1}$.

Definition: Dipath

If all arcs in a path P are forward, then P is a dipath.

Definition: Dicircuit

A dipath that is a circuit.

Definition: Degree

The degree of a vertex v of a graph G is the number of edges incident with v , denoted $\deg_G(v)$.

Definition: Subgraph

H is a subgraph of G if $E(H) \subseteq E(G)$ and $V(H) \subseteq V(G)$.

Definition: Spanning Subgraph

H is spanning if $V(H) = V(G)$.

Definition: Path

A sequence $P = v_0, e_1, v_1, \dots, e_k, v_k$ where $v_0, \dots, v_k \in V(G)$, $e_1, \dots, e_k \in E(G)$, and $e_i = v_{i-1}v_i$.

We call P a v_0v_k -path. The length of P is the number of edges in P .

Definition: Simple Path

A path $v_0, e_1, v_1, \dots, e_k, v_k$ where all v_i are distinct.

Definition: Edge-Simple Path

A path $v_0, e_1, v_1, \dots, e_k, v_k$ where all e_i are distinct.

Definition: Closed Path

A path $v_0, e_1, v_1, \dots, e_k, v_k$ where $v_0 = v_k$.

Definition: Circuit/Cycle

An edge-simple, closed path where v_0, \dots, v_{k-1} are distinct.

Definition: Connected

A graph is connected if every pair of vertices is joined by a path.

Theorem

A graph G is connected if and only if there is no set $A \subseteq V$ where $\emptyset \neq A \neq V$ with $\delta(A) = \emptyset$.

Definition: Connected Component

A maximal connected subgraph.

Definition: Cut Vertex

A vertex v of a connected graph G where $G - v$ is not connected.

Definition: Forest

A graph with no circuits.

Definition: Tree

A connected forest.

Definition: Cut

Let $R \subseteq V$, then

$$\delta(R) = \{vw : vw \in E, v \in R, w \notin R\}$$

Definition: rs -Cut

A cut for which $r \in R, s \notin R$.

Definition: Directed Spanning Tree

A directed spanning tree rooted at r is a spanning tree that contains a dipath from r to each $v \in V$.

Chapter 4

Complexity Classes

Definition: Decision Problem

A problem with a yes-no answer.

Definition: \mathcal{P}

Decision problems that can be solved in polynomial time.

Definition: \mathcal{NP}

Decision problems in which we can certify the answer is yes in polynomial time.

Definition: $\text{co-}\mathcal{NP}$

Decision problems in which we can certify the answer is no in polynomial time.

A good characterization means the problem is in $\mathcal{NP} \cap \text{co-}\mathcal{NP}$.

Definition: \mathcal{NP} -Hard

A problem X is \mathcal{NP} -hard if every other problem Y in \mathcal{NP} can be reduced to X .

S. Cook (1971) proved that the satisfiability problem (SAT) is \mathcal{NP} -hard. R. Karp (1972) used Cook's result to show 21 well-known combinatorial optimization problems are also \mathcal{NP} -hard.

To show that the traveling salesman problem (TSP) is \mathcal{NP} -hard, we show that any example of SAT can be formulated as a TSP, of size polynomial in the size of SAT. Then, since Cook shows SAT is \mathcal{NP} -hard, TSP is also \mathcal{NP} -hard.

Part II

Polyhedral Combinatorics

Chapter 5

Integrality of Polyhedra

5.1 Convex Hull

Definition: Convex Combination

$x = \lambda_1 v_1 + \cdots + \lambda_k v_k$ for some vectors v_1, \dots, v_k and nonnegative scalars $\lambda_1, \dots, \lambda_k$ such that $\lambda_1 + \cdots + \lambda_k = 1$.

Definition: Convex Hull

The convex hull of a finite set S , denoted $\text{conv.hull}(S)$, is the set of all vectors that can be written as a convex combination of S .

It is also defined as the smallest convex set containing S .

Proposition

Let $S \subseteq \mathbb{R}^n$ be a finite set and let $w \in \mathbb{R}^n$. Then

$$\max / \min \{w^T x : x \in S\} = \max / \min \{w^T x : x \in \text{conv.hull}(S)\}$$

Theorem (Minkowski)

If S is finite, then $\text{conv.hull}(S)$ is a polyhedron.

$$\begin{aligned} \max \{w^T x : x \in S\} &= \max \{w^T x : x \in \text{conv.hull}(S)\} \\ &= \max \{w^T x : Ax \leq b\} \\ &= \min \{y^T b : y^T A = w^T, y \geq 0\} \end{aligned}$$

So we can use LP duality to attack combinatorial problems. If we understand $Ax \leq b$, then the problem is in $\text{co-}\mathcal{NP}$. Thus, if we have an algorithm to produce the inequalities in $Ax \leq b$ (separation), then the problem is in \mathcal{P} (Ellipsoid method).

5.2 Polytopes

Definition: Polyhedron

A set of the form $\{x : Ax \leq b\}$.

In combinatorial optimization, we typically have $x \geq 0$ as a constraint, so we have polyhedra of the form $\{x : Ax \leq b, x \geq 0\}$.

Definition: Polytope

A polyhedron $P \subseteq \mathbb{R}^n$ is a polytope if there exists $\ell, u \in \mathbb{R}^n$ such that $\ell \leq x \leq u$ for all $x \in P$.

Definition: Convex Set

Let P be a polyhedron, $x_1, x_2 \in P$, and $0 \leq \lambda \leq 1$. If $\lambda x_1 + (1 - \lambda)x_2 \in P$, then P is a convex set.

Definition: Valid Inequality

An inequality $w^T x \leq t$ is valid for a polyhedron P if $P \subseteq \{x : w^T x \leq t\}$.

Definition: Hyperplane

The solution set of $w^T x = t$ where $w \neq 0$.

Definition: Supporting Hyperplane

With respect to a polyhedron P , a hyperplane is supporting if $w^T x \leq t$ is valid for P and $P \cap \{x : w^T x = t\} \neq \emptyset$.

Definition: Face

The intersection of a polyhedron with one of its supporting hyperplanes.

The null set and the polyhedron itself is a face.

Definition: Proper Face

Faces which are not the null set or the polyhedron itself.

Proposition

A nonempty set $F \subseteq P = \{x : Ax \leq b\}$ is a face of P if and only if for some subsystem $A^\circ x \leq b^\circ$ of $Ax \leq b$, we have $F = \{x \in P : A^\circ x = b^\circ\}$.

Proof. (\implies) Suppose F is a face of P . Then there exists a valid inequality $w^T x \leq t$ such that $F = \{x \in P : w^T x = t\}$.

Consider the LP problem $\max\{w^T x : Ax \leq b\}$. The set of optimal solutions is precisely F . Now let y^* be an optimal solution to the dual problem $\min\{y^T b : y^T A = w, y \geq 0\}$ and let $A^\circ x \leq b^\circ$ be those inequalities $a_i^T x \leq b_i$ whose corresponding dual variable y_i^* is positive. By complementary slackness, we have $F = \{x : Ax \leq b, A^\circ x = b^\circ\}$ as required.

(\Leftarrow) Conversely, if $F = \{x \in P : A^\circ x = b^\circ\}$ for some subsystem $A^\circ x \leq b^\circ$ of $Ax \leq b$, then add the inequalities $A^\circ x \leq b^\circ$ to obtain an inequality $w^T x \leq t$. Every $x \in F$ satisfies $w^T x = t$ and every $x \in P \setminus F$ satisfies $w^T x < t$ as required. \square

Proposition

Let F be a minimal nonempty face of $P = \{x : Ax \leq b\}$. Then $F = \{x : A^\circ x = b^\circ\}$ for some subsystem $A^\circ x \leq b^\circ$ of $Ax \leq b$.
Moreover, the rank of the matrix A° is equal to the rank of A .

Definition: Vertex/Extreme Point

A vector $x \in P$ is called a vertex/extreme point if $\{x\}$ is a face of P .
Equivalently, $x \in P$ is a vertex/extreme point if x cannot be written as $\frac{1}{2}x_1 + \frac{1}{2}x_2$ for points $x_1, x_2 \in P, x_1 \neq x_2$.

Note: Not all polyhedra have vertices, but if $P \subseteq \mathbb{R}_+^n$, then P has vertices.

LP Fact

If a polyhedron P has vertices, then the set of optimal LP solutions contains at least one vertex of P .
Moreover, if all vertices of P are integral, then the LP always has an integral optimal solution.

Definition: Pointed Polyhedron

A polyhedron P is pointed if it has at least one vertex.

$\{(x_1, x_2) \in \mathbb{R}^2 : x_1 \geq 0\}$ is a polyhedron with no vertex.

Proposition

If a polyhedron P is pointed, then every minimal nonempty face of P is a vertex.

Proposition

Let $P = \{x : Ax \leq b\}$ and $v \in P$. Then v is a vertex of P if and only if v cannot be written as a convex combination of vectors in $P \setminus \{v\}$.

Theorem

A polytope is equal to the convex hull of its vertices.

Proof. Let P be a nonempty polytope. Since P is bounded, P must be pointed. Let

v_1, \dots, v_k be the vertices of P . Clearly, $\text{conv.hull}(\{v_1, \dots, v_k\}) \subseteq P$. So suppose there exists

$$u \in P \setminus \text{conv.hull}(\{v_1, \dots, v_k\})$$

Then by proposition, there exists an inequality $w^T x \leq t$ that separates u from

$$\text{conv.hull}(\{v_1, \dots, v_k\})$$

Let $t^* = \max\{w^T x : x \in P\}$ and consider the face $F = \{x \in P : w^T x = t^*\}$. Since $u \in P$, we have $t^* > t$. So F contains no vertex of P , a contradiction. \square

Theorem

A set P is a polytope if and only if there exists a finite set V such that P is the convex hull of V .

5.3 Integral Polytopes

Definition: Rational Polyhedron

A polyhedron that can be defined by rational linear systems.

Definition: Integral Polyhedron

A rational polyhedron where every nonempty face contains an integral vector.

Definition: Pointed Integral Polyhedron

A pointed rational polyhedron is integral if and only if all its vertices are integral.

Theorem

A rational polytope P is integral if and only if for all integral vectors w , the optimal value of $\max\{w^T x : x \in P\}$ is an integer.

Proof. To prove sufficiency, suppose that for all integral vectors w , the optimal value of $\max\{w^T x : x \in P\}$ is an integer. Let $v = (v_1, \dots, v_n)^T$ be a vertex of P and let w be an integral vector such that v is the unique optimal solution to $\max\{w^T x : x \in P\}$. By multiplying w by a large positive integer if necessary, we may assume $w^T v > w^T u + u_1 - v_1$ for all vertices u of P other than v . This implies that if we let $\bar{w} = (w_1 + 1, w_2, \dots, w_n)^T$, then v is an optimal solution to $\max\{\bar{w}^T x : x \in P\}$. So $\bar{w}^T v = w^T v + v_1$. But, by assumption, $w^T v$ and $\bar{w}^T v$ are integers. Thus, v_1 is an integer. We can repeat this for each component of v , so v must be integral. \square

5.4 Total Unimodularity

Proposition

Let A be an integral, nonsingular, $m \times n$ matrix. Then $A^{-1}b$ is integral for every integral vector $b \in \mathbb{R}^m$ if and only if $\det(A) = 1$ or -1 .

Proof. (\Leftarrow) Suppose $\det(A) = \pm 1$. By Cramer's Rule, we know that A^{-1} is integral, which implies $A^{-1}b$ is integral for every integral b .

(\Rightarrow) Conversely, suppose $A^{-1}b$ is integral for all integral vectors b . Then, in particular, $A^{-1}e_i$ is integral for all $i = 1, \dots, m$. This means that A^{-1} is integral. So $\det(A)$ and $\det(A^{-1})$ are both integers. But, $\det(A) \cdot \det(A^{-1}) = 1$, this implies $\det(A) = \pm 1$. \square

Definition: Unimodular

A matrix A of full row rank is unimodular if A is integral and each basis of A has determinant ± 1 .

Theorem (Veinott & Dantzig 1968)

Let A be an integral $m \times n$ matrix of full row rank. Then the polyhedron defined by $Ax = b, x \geq 0$ is integral for every integral vector $b \in \mathbb{R}^m$ if and only if A is unimodular.

Proof. (\Leftarrow) Suppose A is unimodular. Let $b \in \mathbb{R}^m$ be an integral vector and let \bar{x} be a vertex of $\{x : Ax = b, x \geq 0\}$. The nonnegativity constraints implies the polyhedron has vertices. Then there are n linearly independent constraints satisfied by \bar{x} with inequality. It follows that the columns of A corresponding to the nonzero components of \bar{x} are linearly independent. Extending these columns to a basis B of A , we have the nonzero components of \bar{x} are contained in the integral vector $B^{-1}b$. So \bar{x} is integral.

(\Rightarrow) Conversely, suppose $\{x : Ax = b, x \geq 0\}$ is integral for all integral vectors b . Let B be a basis of A and let v be an integral vector in \mathbb{R}^m . By previous proposition, it suffices to show that $B^{-1}v$ is integral. Let y be an integral vector such that $y + B^{-1}v \geq 0$ and let $b = B(y + B^{-1}v)$. Note b is integral. Furthermore, by adding zero components to the vector $y + B^{-1}v$, we can obtain a vector $z \in \mathbb{R}^n$ such that $Az = b$. Then, z is a vertex of $\{x : Ax = b, x \geq 0\}$, since z is a polyhedron and satisfies n linearly independent constraints with equality: the m equations $Ax = b$ and the $n - m$ equations $x_i = 0$ for the columns i outside B . So z is integral, and thus, $B^{-1}v$ is integral. \square

Definition: Totally Unimodular (TU)

A matrix is totally unimodular if all of its square submatrices have determinant 0, 1, or -1 .

It is easy to see that A is totally unimodular if and only if $\begin{bmatrix} A & I \end{bmatrix}$ is unimodular where $I \in \mathbb{R}^{m \times m}$.

Theorem (Hoffman-Kruskal)

Let A be an $m \times n$ integral matrix. Then the polyhedron defined by $Ax \leq b, x \geq 0$ is integral for every integral vector $b \in \mathbb{R}^m$ if and only if A is totally unimodular.

Proof. Applying the linear programming trick of adding slack variables, we have that for any integral b , the polyhedron $\{x : Ax \leq b, x \geq 0\}$ is integral if and only if the polyhedron $\{z : \begin{bmatrix} A & I \end{bmatrix} z = b, z \geq 0\}$ is integral. So the result follows from previous theorem. \square

Theorem

Let A be an $m \times n$ totally unimodular matrix and let $b \in \mathbb{R}^m$ be an integral vector. Then the polyhedron defined by $Ax \leq b$ is integral.

Proof. Let F be a minimal face of $\{x : Ax \leq b\}$. Then, by proposition, $F = \{x : A^\circ x = b^\circ\}$ for some subsystem $A^\circ x \leq b^\circ$ of $Ax \leq b$, with A° having full row rank. By reordering the columns, if necessary, we may write A° as $\begin{bmatrix} B & N \end{bmatrix}$ where B is a basis of A° . It follows

$$\bar{x} = \begin{bmatrix} B^{-1}b^\circ \\ 0 \end{bmatrix}$$

is an integral vector in F . \square

Theorem

Let A be a $0, \pm 1$ valued matrix where each column has at most one $+1$ and at most -1 . Then A is totally unimodular.

Proof. Let N be a $k \times k$ submatrix of A . If $k = 1$, then $\det(N)$ is either 0 or ± 1 . So we may suppose that $k \geq 2$ and proceed by induction on k . If N has a column having at most one nonzero, then expanding the determinant along this column, we have that $\det(N)$ is either 0 or ± 1 , by induction. On the other hand, if every column of N has both a $+1$ and a -1 , then the sum of the rows of N is 0 and hence $\det(N) = 0$. \square

Proposition

A is totally unimodular if and only if A^T is totally unimodular.

5.5 Optimization and Separation

There are many ways to be given a polyhedron P . Either in the form $\{x : Ax \leq b\}$, $\text{conv.hull}(\{a_1, \dots, a_m\})$, or a graph's convex hull of matchings or TSP tours.

Optimization Problem

Given a bounded rational polyhedron $P \subseteq \mathbb{R}^n$ and a rational objective vector $c \in \mathbb{Q}^n$, solve $\max\{c^T x : x \in P\}$.

Separation Problem

Given a bounded rational polyhedron $P \subseteq \mathbb{R}^n$ and a rational vector $\bar{x} \in \mathbb{Q}^n$, either

1. assert $\bar{x} \in P$, or
2. find $c \in \mathbb{Q}^n, \delta \in \mathbb{Q}$ such that $c^T x \leq \delta$ is satisfied for all $x \in P$ (valid) and $c^T \bar{x} > \delta$ (violated by \bar{x}).

Such a $c^T x \leq \delta$ is called a separating inequality and a $c^T x = \delta$ is called a separating hyperplane.

Definition: Well-Described Polyhedron

A triple (P, n, φ) where $P \subseteq \mathbb{Q}^n$ is a rational polyhedron with facet complexity at most φ .

Theorem (Grötschel, Lovász, Schrijver 1982)

For a well-described polyhedron, optimization can be solved in polynomial time if and only if separation can be solved in polynomial time.

This theorem is known as the optimization \equiv separation theorem. We can use the ellipsoid method for solving LPs.

This is a fantastic result, as it shows that polynomial time solvability for combinatorial problems, such as TSP or matchings, is directly tied to our ability to understanding the convex hull of solutions. This is due to Minkowski.

Edmonds gives a polynomial time optimization for $\mathcal{PM}(G)$ and by GLS, we have a polynomial time separation for $\mathcal{PM}(G)$. But it is much easier to go the other way, first describing a polynomial time separation algorithm.

5.6 Total Dual Integrality

Definition: Totally Dual Integral (TDI)

A rational linear system $Ax \leq b$ is totally dual integral if for every integral w such that the dual LP

$$\min\{y^T b : y^T A = w^T, y \geq 0\}$$

has an optimal solution, it has an optimal solution that integer valued.

Theorem (Total Dual Integrality Theorem)

If $Ax \leq b$ is totally dual integral and b is integral, then the polyhedron $P = \{x : Ax \leq b\}$ is integral.

Proof. If $Ax \leq b$ is TDI and b is integral, then for all integral w such that the optima exist, both sides of the duality equation

$$\max\{w^T x : Ax \leq b\} = \min\{y^T b : y^T A = w^T, y \geq 0\}$$

have integer optimal solutions. □

Proving a system is TDI is one way to prove that a polyhedron is integral.

Part III

Optimal Trees and Paths

Chapter 6

Minimum Spanning Trees

6.1 Problem

Definition: Spanning Tree

A subgraph $T \subseteq G$ where $V(T) = V(G)$, T is connected, and T is acyclic.

Lemma

An edge $e = uv$ of G is an edge of a circuit of G if and only if there is a path in $G \setminus e$ from u to v .

Minimum Spanning Tree Problem (MST)

Given a connected graph G and a real cost c_e for each $e \in E$, find a minimum cost spanning tree of G .

Lemma

A spanning connected subgraph of G is a spanning tree if and only if it has exactly $n - 1$ edges.

6.2 Kruskal's Algorithm

Theorem

Kruskal's algorithm finds a MST.

This is a polynomial time algorithm and is very fast in practice for sparse graphs. We can maintain F with a union-find data structure.

Algorithm 1 Kruskal's Algorithm (Minimum Spanning Tree)

```
1: Sort  $E$  to  $\{e_1, \dots, e_m\}$  so that  $c_{e_1} \leq \dots \leq c_{e_m}$ 
2:  $F = \emptyset, H = (V, F)$ 
3: for  $i = 1$  to  $m$  do
4:   if ends of  $e_i$  are in different components of  $H$  then
5:      $F \leftarrow F \cup \{e_i\}$ 
6: return  $H$ 
```

6.3 Linear Programming

Definition: $\kappa : E \rightarrow \mathbb{N}$

For $A \subseteq E$, $\kappa(A)$ is the number of components in the subgraph (V, A) of G .

The maximum number of tree edges in A is $|V| - \kappa(A)$.

We can formulate the MST problem as an ILP.

$$\begin{aligned} \min \quad & c^T x \\ \text{s.t.} \quad & \sum (x_e : e \in A) \leq |V| - \kappa(A), \quad \forall A \subsetneq E \\ & \sum (x_e : e \in E) = |V| - 1 \\ & x_e \in \{0, 1\}, \quad \forall e \in E \end{aligned}$$

We can relax the integer program to get the following linear program.

Definition: MST LP

$$\begin{aligned} \min \quad & c^T x \\ \text{s.t.} \quad & x(A) \leq |V| - \kappa(A), \quad \forall A \subsetneq E \\ & x(E) = |V| - 1 \\ & x_e \geq 0, \quad \forall e \in E \end{aligned}$$

We replace the minimization with a maximization in the primal to write the dual.

Definition: MST Dual LP

$$\begin{aligned} \min \quad & \sum ((|V| - \kappa(A))y_A : A \subseteq E) \\ \text{s.t.} \quad & \sum (y_A : e \in A) \geq -c_e, \quad \forall e \in E \\ & y_A \geq 0, \quad \forall A \subsetneq E \end{aligned}$$

6.3.1 Complementary Slackness Conditions

Let T be a tree found by Kruskal's algorithm. Define the characteristic vector of T

$$x_e^0 = \begin{cases} 1 & \text{if } e \in E(T) \\ 0 & \text{if } e \notin E(T) \end{cases}$$

Definition: MST Complementary Slackness Conditions

- (i) For all $e \in E$, if $x_e^0 > 0$, then $\sum(y_A^0 : e \in A) = -c_e$.
- (ii) For all $A \subsetneq E$, if $y_A^0 > 0$, then $\sum(x_e^0 : e \in A) = |V| - \kappa(A)$.

Theorem (Edmonds 1971)

Let x^0 be the characteristic vector of an MST with respect to costs c_e . Then x^0 is an optimal solution to the MST LP.

Proof. We show that x^0 is optimal for the LP and x^0 is the characteristic vector generated by Kruskal's algorithm.

Let e_1, \dots, e_m be the order in which Kruskal's algorithm considers the edges. Let $R_i = \{e_1, \dots, e_i\}$ for $1 \leq i \leq m$. Let y^0 be the dual solution.

- $y_A^0 = 0$ if A is not one of the R_i 's.
- $y_{R_i}^0 = c_{e_{i+1}} - c_{e_i}$ for $1 \leq i \leq m-1$.
- $y_{R_m}^0 = -c_{e_m}$

It follows from the ordering of the edges, $y_A^0 \geq 0$ for $A \neq E$. Now consider the first constraint, then where $e = e_i$, we have

$$\sum(y_A^0 : e \in A) = \sum_{j=i}^m y_{R_j}^0 = \sum_{j=i}^{m-1} (c_{e_{j+1}} - c_{e_j}) - c_{e_m} = -c_{e_i} = -c_e$$

All of the inequalities hold with equality. So y^0 is a feasible dual solution and complementary slackness condition (i) holds.

Now suppose $y_A^0 > 0$ for some $A \subsetneq E$. Thus, $A = R_i$ for some i . Consider the constraint

$$\sum(x_e^0 : e \in R_i) \leq |V| - \kappa(R_i)$$

If this does not hold with equality, then there is some edge of R_i having ends in two different components of $(V, R_i \cap T)$ and this would have been added to T by Kruskal's algorithm. So (x^0, y^0) satisfy the complementary slackness conditions, which means they are optimal solutions to their LPs. Therefore, T is an MST. \square

6.4 Spanning Tree Polytope

Definition: Spanning Tree Polytope

$\text{conv.hull}\{x^H : H \text{ is a spanning tree}\}$ where

$$x_e^H = \begin{cases} 1 & \text{if } e \in E(H) \\ 0 & \text{if } e \notin E(H) \end{cases}$$

Theorem

The spanning tree polytope is the solution set to the following linear system:

$$\begin{aligned} \sum(x_e : e \in A) &\leq |V| - \kappa(A), \quad \forall A \subsetneq E \\ \sum(x_e : e \in E) &= |V| - 1 \\ x_e &\geq 0, \quad \forall e \in E \end{aligned}$$

Proof. Let P be the solution set of the linear system. We showed that for any edge costs $(c_e : e \in E)$, the LP

$$\max\{\sum(-c_e x_e : e \in E) : x \in P\}$$

has an integral optimal solution. So every vertex of P is integral. \square

Chapter 7

Shortest Paths

Shortest Path Problem

Given a digraph G , a vertex $r \in V$, and a real cost vector $(c_e : e \in E)$, find for each $v \in V$, a minimum-cost dipath from r to v .

Note: You can provide a solution to the shortest path problem for r by giving a directed spanning tree rooted at r .

Proof. For each $v \in V \setminus \{r\}$, all shortest paths have at most one arc having head v_j , since the only such arc we need is the last arc of one min-cost rv -dipath.

So the union of the arc sets of all the shortest paths has exactly $|V| - 1$ arcs and thus is a tree. \square

Important Case

If $c_e \geq 0$ for all $e \in E$, then this problem is handled by Dijkstra's algorithm, which starts at r and grows the tree vertex by vertex.

However, the Hamiltonian dipath problem (does G have a simple dipath P with $V(P) = V(G)$) is \mathcal{NP} -hard.

When G has negative-cost dicircuits, this is a problem, since there is no shortest path as we can loop around the dicircuit an infinite amount of times. There do exist polynomial time algorithms that either finds a shortest path or detect a negative-cost dicircuit.

Definition: Feasible Potential

$y = (y_v : v \in V)$ is a feasible potential if it satisfies $y_v + c_{vw} \geq y_w$ for all $vw \in E$.

Proposition

Let y be a feasible potential and let P be an rs -dipath. Then $c(P) \geq y_s - y_r$.

Proof. Suppose that P is $v_0, e_1, v_1, \dots, e_k, v_k$ where $v_0 = r$ and $v_k = s$. Then

$$c(P) = \sum_{i=1}^k c_{e_i} \geq \sum_{i=1}^k (y_{v_i} - y_{v_{i-1}}) = y_{v_k} - y_{v_0} = y_s - y_r$$

□

So a potential y provides a stopping rule. A dipath P and a potential y with $c(P) = y_s - y_r$ implies P is optimal.

7.1 Ford's Algorithm

Definition: Incorrect

Given vertex values $(y_v : v \in V)$, the edge vw is incorrect if $y_v + c_{vw} < y_w$.

To correct vw , we set $y_w = y_v + c_{vw}$ and $\text{predecessor}(w) = v$.

Algorithm 2 Ford's Algorithm (Shortest Path)

- 1: $y_r = 0, y_v = \infty$ for all $v \in V \setminus \{r\}$
 - 2: $\text{predecessor}(r) = \emptyset, \text{predecessor}(v) = -1$ for all $v \in V \setminus \{r\}$
 - 3: **while** y is not a feasible potential **do**
 - 4: Find an incorrect arc vw and correct vw
-

Theorem

If there are no negative-cost dicircuits, then Ford's algorithm terminates in a finite number of steps.

At termination, for each $v \in V$, the predecessors define a shortest rv -dipath of cost y_v .

Specialized versions like Ford-Bellman run in polynomial time.

7.2 Linear Programming

Definition: Shortest Path LP

$$\begin{array}{ll} \max & y_s - y_r \\ \text{s.t.} & y_w - y_v \leq c_{vw}, \quad \forall vw \in E \end{array}$$

Definition: Shortest Path Dual LP

$$\begin{aligned}
\min \quad & \sum (c_e x_e : e \in E) \\
\text{s.t.} \quad & \sum (x_{wv} : wv \in E) - \sum (x_{vw} : vw \in E) = \begin{cases} 0 & \text{if } v \in V \setminus \{r, s\} \\ -1 & \text{if } v = r \\ 1 & \text{if } v = s \end{cases} \\
& x_{vw} \geq 0, \forall vw \in E
\end{aligned}$$

Any rs -dipath is a solution to the dual LP, so if the dual LP has an optimal solution, then it has an optimal solution that is an rs -dipath.

The constraint matrix for the LP is totally unimodular.

Theorem

Let G be a digraph, $r, s \in V$, and $c \in \mathbb{R}^E$. If there exists a minimum-cost dipath from r to v for every $v \in V$, then

$$\min\{c(P) : P \text{ an } rs\text{-dipath}\} = \max\{y_s : y \text{ a feasible potential}\}$$

The vertices of the polyhedron defined by the dual LP constraints are the vectors x^P of simple dipaths.

$$x_e^P = \begin{cases} 1 & \text{if } e \in E(P) \\ 0 & \text{if } e \notin E(P) \end{cases}$$

Note: This is *not* the convex hull of simple dipaths.

Since the matrix is totally unimodular, we could add $x_{vw} \leq 1$ for all $vw \in E$, but this will not give simple dipaths.

Part IV

Network Flows

Chapter 8

Maximum Flow

8.1 Problem

Definition: Net Flow/Excess

$$f_x(v) = x(\delta(\bar{v})) - x(\delta(v)) = \sum(x_{wv} : w \in V, wv \in E) - \sum(x_{vw} : w \in V, vw \in E)$$

Definition: rs -Flow

A vector x that satisfies $f_x(v) = 0$ for all $v \in V$.

Definition: Value of rs -Flow

$$f_x(s)$$

Maximum Flow Problem

Given a digraph $G = (V, E)$, with source r and sink s , find an rs -flow of maximum value.

8.2 Augmenting Path Algorithm

Definition: Augmenting Path

An rs -path P is x -augmenting if for all forward arcs e we have $x_e < u_e$, and for all reverse arcs e we have $x_e > 0$.

Given a flow $x = (x_e : e \in E)$ and augmenting path P , we can augment flow x by the largest ε . There is some forward arc with $x_e + \varepsilon = u_e$ or some reverse arc has $x_e - \varepsilon = 0$. The value ε is called the x -width of P .

Algorithm 3 Ford-Fulkerson Algorithm (Maximum Flow/Minimum Cut)

```
1:  $x = 0$ 
2: while there is an  $x$ -augmenting path  $P$  do
3:    $\varepsilon_1 = \min(u_e - x_e : e \text{ forward in } P)$ 
4:    $\varepsilon_2 = \min(x_e : e \text{ reverse in } P)$ 
5:    $\varepsilon = \min(\varepsilon_1, \varepsilon_2)$  //  $x$ -width of  $P$ 
6:   if  $\varepsilon = \infty$  then
7:     No maximum flow
8: return  $x$  is maximum flow, set  $R$  of vertices reachable by an  $x$ -augmenting path from  $r$ 
   is minimum cut
```

Definition: Auxiliary Digraph

$G(x)$, depending on G, u, x , where $V(G(x)) = V$ and $vw \in E(G(x))$ if and only if $vw \in E$ and $x_{vw} < u_{vw}$ or $wv \in E$ and $x_{wv} > 0$.

rs -dipaths in $G(x)$ corresponding to x -augmenting paths in G . Each iteration of Ford-Fulkerson can be performed in $O(m)$ time, using breadth-first search.

Theorem

If u is integral and the maximum flow value is $K < \infty$, then the maximum flow algorithm terminates after at most K augmentations.

8.2.1 Shortest Augmenting Paths

Theorem (Dinits 1970, Edmonds & Karp 1972)

If each augmentation of the augmenting path algorithm on a shortest augmenting path, then there are at most nm augmentations.

Corollary

The augmenting path algorithm with breadth-first search solves the maximum flow problem in time $O(nm^2)$.

Let $d_x(v, w)$ be the least length of a vw -dipath in $G(x)$. $d_x(v, w) = \infty$ if no vw -dipath exists.

Consider a typical augmentation from flow x to flow x' determined by the augmenting path P having vertex-sequence v_0, \dots, v_k .

Lemma

For each $v \in V$, $d_{x'}(r, v) \geq d_x(r, v)$ and $d_{x'}(v, s) \geq d_x(v, s)$.

Proof. Suppose that there exists a vertex v such that $d_{x'}(r, v) < d_x(r, v)$ and choose such v so that $d_{x'}(r, v)$ is as small as possible. Clearly, $d_{x'}(r, v) > 0$. Let P' be a rv -dipath in $G(x')$

of length $d_{x'}(r, v)$ and let w be the second-last vertex of P' . Then

$$d_x(r, v) > d_{x'}(r, v) = d_{x'}(r, w) + 1 \geq d_x(r, w) + 1$$

It follows that wv is an arc of $G(x')$, but not of $G(x)$, otherwise $d_x(r, v) \leq d_x(r, w) + 1$, so $w = v_i$ and $v = v_{i-1}$ for some i . But, this implies that $i - 1 > i + 1$, a contradiction. The second statement is similar. \square

Definition: $\tilde{E}(x)$

$$\tilde{E}(x) = \{e \in E : e \text{ is an arc of a shortest } x\text{-augmenting path}\}$$

Lemma

If $d_{x'}(r, s) = d_x(r, s)$, then $\tilde{E}(x') \subsetneq \tilde{E}(x)$.

Proof. Let $k = d_x(r, s)$ and suppose that $e \in \tilde{E}(x')$. Then e induces an arc vw of $G(x')$ and $d_{x'}(r, v) = i - 1$, $d_{x'}(ws) = k - i$ for some i . Therefore, $d_x(r, v) + d_x(w, s) \leq k - 1$ by previous lemma. Now suppose that $e \notin \tilde{E}(x)$, then $x_e \neq x'_e$, so e is an arc of P , a contradiction. This proves $\tilde{E}(x') \subseteq \tilde{E}(x)$.

There is an arc e of P such that e is forward and $x'_e = u_e$ or e is reverse and $x'_e = 0$. Therefore, any x' -augmenting path using e must use it in the opposite direction from P , so its length, for some i , will be at least $i + k - i + 1 + 1 = k + 23$, so $e \notin \tilde{E}(x')$. \square

Proof. (Dinitz, Edmonds, Karp) It follows from previous lemma that there can be at most m augmentations per stage. Since there are at most $n - 1$ stages, there are at most nm augmentations in all. \square

8.3 Linear Programming

Definition: Maximum Flow LP

$$\begin{aligned} \max \quad & f_x(s) \\ \text{s.t.} \quad & f_x(v) = 0, \forall v \in V \setminus \{r, s\} \\ & 0 \leq x_e \leq u_e, \forall e \in E \end{aligned}$$

We give a different LP approach to this problem.

Definition: Minimum Cut LP

$$\begin{aligned} \min \quad & \sum (u_e y_e : e \in E) \\ \text{s.t.} \quad & \sum (y_e : e \in E(P)) \geq 1, \forall \text{ } rs\text{-simple dipaths } P \\ & y_e \geq 0, \forall e \in E \end{aligned}$$

Every rs -cut $\delta(R)$ gives a feasible solution

$$y_e^R = \begin{cases} 1 & \text{if } e \in \delta(R) \\ 0 & \text{if } e \notin \delta(R) \end{cases}$$

Definition: Maximum Flow LP (Dual Minimum Cut LP)

$$\begin{aligned} \max \quad & \sum (w_P : P \text{ a simple } rs\text{-dipath}) \\ \text{s.t.} \quad & \sum (w_P : e \in E(P)) \leq u_e, \forall e \in E \\ & w_P \geq 0, \forall \text{ simple dipaths } P \end{aligned}$$

Let x be a max flow. We want to find a simple rs -dipath P such that $x_e > 0$ for each $e \in E(P)$. Set $w_P = \min\{x_e : e \in E(P)\}$ and let $x_e = x_e - w_P$ for all $e \in E(P)$. We repeat until $\sum (x_{rv} : rv \in E) = 0$.

$\sum (w_P : P \text{ a simple } rs\text{-dipath})$ is equal to the original value of the flow. Therefore, the max flow equals the min cut which implies the two LPs have integral optimal solutions if u_e is integral for all $e \in E$.

Proposition

There exists a family (P_1, \dots, P_k) of rs -dipaths such that $|\{i : e \in P_i\}| \leq u_e$ for all $e \in E$ if and only if there exists an integral feasible rs -flow of value k .

Proof. (\implies) We have seen family of dipaths determines a corresponding flow.

(\impliedby) Let x be a flow. We assume that x is acyclic, that is, there is no dicircuit C , each of whose arcs e has $x_e > 0$. If a dicircuit does exist, we can decrease x_e by 1 on all arcs of C . The new x remains feasible of value k .

If $k \geq 1$, we can find an arc vs with $x_{vs} \geq 1$. Then, if $v \neq r$, it follows that there is an arc wv with $x_{wv} \geq 1$ by the constraint $f_x(v) = 0$. If $w \neq r$, then the argument can be repeated producing distinct vertices, since x is acyclic, so we get a simple rs -dipath P_k on each arc e with $x_e \geq 1$. We can decrease x_e by 1 for each $e \in P_k$. The new x is an integral feasible flow of value $k - 1$, and the process is repeated. \square

Definition: Path Flow

A vector $x \in \mathbb{R}^E$ such that for some rs -dipath P and some $\alpha \in \mathbb{R}$, $x_e = \alpha$ for each $e \in P$ and $x_e = 0$ for every other arc of G .

Definition: Circuit Flow

A vector $x \in \mathbb{R}^E$ such that for some rs -dicircuit C and some $\alpha \in \mathbb{R}$, $x_e = \alpha$ for each $e \in C$ and $x_e = 0$ for every other arc of G .

Proposition

Every rs -flow of nonnegative value is the sum of at most m flows, each of which is a path flow or a circuit flow.

Proposition

For any rs -cut $\delta(R)$ and any rs -flow x , we have

$$f_x(s) = x(\delta(R)) - x(\delta(\bar{R}))$$

Proof. We add the equations $f_x(v) = 0$ for all $v \in \bar{R} \setminus \{s\}$ as well as the identity $f_x(s) = f_x(s)$. The right hand side sums to $f_x(s)$.

For any arc vw with $v, w \in R$, x_{vw} occurs in none of the equations, so it does not occur in the sum. If $v, w \in \bar{R}$, then x_{vw} occurs in the equation for v with a coefficient of -1 , and in the equation for w with a coefficient of $+1$, so it has a coefficient of 0 in the sum. If $v \in R, w \notin R$, then x_{vw} occurs in the equation for w with a coefficient of 1 , and so has coefficient 1 in the sum. If $v \notin R, w \in R$, then x_{vw} occurs in the sum with a coefficient of -1 . So, the left hand side sums to $x(\delta(R)) - x(\delta(\bar{R}))$, as required. \square

Corollary

For any feasible rs -flow x and any rs -cut $\delta(R)$,

$$f_x(s) \leq u(\delta(R))$$

Proof. Using previous proposition, since $x(\delta(R)) \leq u(\delta(R))$ and $x(\delta(\bar{R})) \geq 0$. \square

Theorem (Max-Flow Min-Cut)

If there is a maximum rs -flow, then

$$\max\{f_x(s) : x \text{ is a feasible } rs\text{-flow}\} = \min\{u(\delta(R)) : \delta(R) \text{ is an } rs\text{-cut}\}$$

Proof. By previous corollary, we need only show that there exists a feasible flow x and a cut $\delta(R)$ such that $f_x(s) = u(\delta(R))$. Let x be a flow of maximum value. Let $R = \{v \in V : \text{there exists an } x\text{-augmenting } rv\text{-path}\}$. Clearly $r \in R$ and $s \notin R$, since there can be no x -augmenting path.

For every arc $vw \in \delta(R)$, we must have $x_{vw} = u_{vw}$, since otherwise adding vw to the x -augmenting rv -path would yield such a path to w , but $w \notin R$. Similar, for every arc $vw \in \delta(\bar{R})$, we have $x_{vw} = 0$. Then by proposition, $f_x(s) = x(\delta(R)) - x(\delta(\bar{R})) = u(\delta(R))$. \square

Theorem

A feasible flow x is maximum if and only if there is not x -augmenting path.

Proof. (\implies) If x is maximum, there is no x -augmenting path.

(\Leftarrow) If there is no x -augmenting path, then the construction of the proof of Max-Flow Min-Cut yields a cut $\delta(R)$ with $f_x(s) = u(\delta(R))$, so x is maximum, by corollary. \square

Theorem

If u is integral and there exists a maximum flow, then there exists a maximum flow that is integral.

Proof. Choose an integral flow x of maximum value. If there is an x -augmenting path, then since x and u are integral, the new flow can be chosen integral, contradicting the choice of x . Hence there is no x -augmenting path, so x is a maximum flow, by previous theorem. \square

Corollary

If x is a feasible rs -flow and $\delta(R)$ is an rs -cut, then x is maximum and $\delta(R)$ is minimum if and only if $x_e = u_e$ for all $e \in \delta(R)$ and $x_e = 0$ for all $e \in \delta(\overline{R})$.

Proof. Combine Max-Flow Min-Cut theorem with the proof of corollary. \square

Part V

Matchings

Chapter 9

Matchings

Definition: Matching

A set $M \subseteq E$ such that no vertex of G is incident with more than one edge in M .

Definition: M -Covered

A vertex v is covered by M if some edge of M is incident with v .

Definition: M -Exposed

A vertex v is exposed if v is not M -covered.

The number of vertices covered by M is $2|M|$ and number of M -exposed vertices is $|V| - 2|M|$.

Definition: Maximum Matching

A matching of maximum cardinality, denoted $\nu(G)$.

Definition: Deficiency

The minimum number of exposed vertices for any matching of G , denoted by $\text{def}(G)$.

Note $\text{def}(G) = |V| - 2\nu(G)$.

Definition: Perfect Matching

A matching that covers all vertices.

Definition: Tight Odd Circuit

An odd circuit C is tight if

$$\nu(G) \geq \nu(G \times C) + \frac{|V(C)| - 1}{2}$$

holds with equality.

Definition: Inessential

A vertex v of G is inessential if there is a maximum matching of G not covering v .

Lemma

Let $G = (V, E)$ be a graph and let $vw \in E$. If v, w are both inessential, then there is a tight odd circuit C using vw .

Moreover, C is an inessential vertex of $G \times C$.

9.1 Bipartite Matching

Definition: Bipartite

$G = (V, E)$ is bipartite if $V = V_1 \cup V_2$, where V_1, V_2 disjoint and every edge has one end in V_1 and the other end in V_2 .

Definition: Vertex Cover

A set $C \subseteq V$ such that every edge has at least one in C .

Lemma

If M is a matching and C is a cover, then $|M| \leq |C|$.

Proof. Every $e \in M$ has at least one end in C . No vertex in C meets more than one edge in M . \square

Definition: Minimum Cover

A cover of minimum cardinality, denoted $\tau(G)$.

Theorem (König)

If G is bipartite, $\nu(G) = \tau(G)$.

Proof. We note that $\nu(G) \leq \nu^*(G)$ and $\tau(G) \geq \tau^*(G)$. By using LP duality and the matching LP (*Matching LP*), we show that $\nu(G) = \nu^*(G)$. We also have the matching LP in the form of $Mx^+ = (1, \dots, 1)^T$. Since M is totally unimodular, then M^T is also totally

unimodular. So the dual LP has all integral vertices, implying $\tau(G) = \tau^*(G)$. So,

$$\nu(G) = \nu^*(G) = \tau^*(G) = \tau(G)$$

□

9.2 Alternating Paths

Definition: M -Alternating

A path P is M -alternating if its edges are alternately in and not in M .

Definition: M -Augmenting

An M -alternating path P is M -augmenting if the ends of P are distinct and are both M -exposed.

Definition: Symmetric Difference

For sets S and T , let $S \Delta T$ denote the symmetric difference, which is defined as

$$S \Delta T = (S \cup T) \setminus (S \cap T)$$

Let a path P be an M -augmenting path. Then we can obtain a larger matching $M' = M \Delta E(P)$ with $|M'| = |M| + 1$.

Theorem (Petersen 1891, Berge 1957)

A matching M in a graph G is maximum if and only if there is no M -augmenting path.

Proof. (\implies) Suppose there exists an M -augmenting path P joining v and w . Then $N = M \Delta E(P)$ is a matching that covers all vertices covered by M , plus v and w . So, M is not maximum.

(\impliedby) Conversely, suppose that M is not maximum and some other matching N satisfies $|N| > |M|$. Let $J = N \Delta M$. Each vertex of G is incident with at most two edges of J , so J is the edge set of some vertex disjoint paths and circuits of G . For each such path or circuit, the edges alternately belong to M or N . Therefore, all circuits are even and contain the same number of edges of M and N . Since $|N| > |M|$, there must be at least one path with more edges of N than M . This path is an M -augmenting path. □

9.3 Matching LP

Definition: Matching LP

P is the set of solutions to

$$\begin{aligned} x(\delta(v)) &\leq 1, \forall v \in V \\ x_e &\geq 0, \forall e \in E \end{aligned}$$

Let \bar{x} be a vertex of P . We show that \bar{x} is integral, which implies that $M = \{e \in E : \bar{x}_e = 1\}$ is a matching and $\nu(G) = \nu^*(G)$.

Recall that for a polyhedron $P = \{x : Ax \leq b\} \subseteq \mathbb{R}^n$, $\bar{x} \in P$ is a vertex if and only if \bar{x} is the unique solution to $A'x = b'$ for some subset of n inequalities $A'x \leq b'$ from $Ax \leq b$.

For our matching P , let $E^+ := \{e : \bar{x}_e > 0\}$ and $E^0 := \{e : \bar{x}_e = 0\}$. We write $\bar{x} = (\bar{x}^+, \bar{x}^0)$ split by (E^+, E^0) .

Since \bar{x} is a vertex, there exists $V^+ \subseteq V$ such that \bar{x} is the unique solution to

$$\begin{aligned} \sum (x_e : e \in \delta(v) \cap E^+) &= 1, \forall v \in V^+ \\ x_e &= 0, \forall e \in E^0 \end{aligned}$$

Restricting to E^+ , we can write the system of equations as

$$Mx^+ = (1, \dots, 1)^T$$

By Cramer's Rule, the solution to the system is $(\bar{x}_1^+, \dots, \bar{x}_k^+)$, where

$$\bar{x}_j^+ = \frac{\det(M^j)}{\det(M)}$$

with M^j obtained from M by replacing the j th column by $(1, \dots, 1)^T$.

Claim: $\det(M) = 1$ or $\det(M) = -1$.

This gives that \bar{x}_j^+ is integer for all j , so \bar{x} is integer. Thus, $\nu(G) = \nu^*(G)$.

Lemma

Let $G = (V, E)$ be a bipartite graph. Let A be the $|V| \times |E|$ matrix $[A_{ve}]$ with

$$A_{ve} = \begin{cases} 1 & \text{if } e \in \delta(v) \\ 0 & \text{if } e \notin \delta(v) \end{cases}$$

then A is totally unimodular.

Proof. By induction of the number of rows k of the submatrix B of A . If B is 1×1 , then this is obvious.

Suppose it is true for $k = 1, \dots, t-1$ and let B be a $t \times t$ submatrix of A .

1. If B has a column of all 0's, then $\det(B) = 0$.
2. If a column of B has exactly one 1, then we compute $\det(B)$ by expanding on that column and use induction.
3. Otherwise, every column of B has exactly two 1's.

We can partition the rows of B into W_1 and W_2 , so that every column has exactly one 1 in W_1 and exactly one 1 in W_2 (W_1 are vertices in V_1 , W_2 in V_2 from G being bipartite).

Now multiplying each row in W_1 by 1 and each row in W_2 by -1 and summing, we get the row vector of all 0's. So $\det(B) = 0$. \square

9.4 Tutte's Theorem

Let A be a subset of the vertices which $G - A$ has k components H_1, \dots, H_k having an odd number of vertices. Let M be a matching of G . For each i , either H_i has an M -exposed vertex or M contains an edge having just one end in $V(H_i)$. All such edges have their other ends in A and since M is a matching, all these ends must be distinct. Therefore, there can be at most $|A|$ edges and so the number of M -exposed vertices is at least $k - |A|$.

Definition: Odd Count $\text{oc}(H)$

The number of components of H that contain an odd number of vertices.

Thus, for any $A \subseteq V$,

$$\nu(G) \leq \frac{1}{2}(|V| - \text{oc}(G - A) + |A|)$$

If A is a cover of G , then there are $|V| - |A|$ odd components of $G - A$ (each is a single vertex), so the right hand side reduces to $|A|$. This bound is at least as strong as that provided by covers.

Theorem (Tutte-Berge Formula)

For a graph $G = (V, E)$, we have

$$\max\{|M| : M \text{ a matching}\} = \min \left\{ \frac{1}{2}(|V| - \text{oc}(G \setminus A) + |A|) : A \subseteq V \right\}$$

Theorem (Tutte's Matching Theorem 1947)

A graph $G = (V, E)$ has a perfect matching if and only if for all $A \subseteq V$, $\text{oc}(G \setminus A) \leq |A|$.

If $\text{oc}(G \setminus A) > |A|$, then A is called a Tutte set.

9.5 Maximum Matching

Maximum Matching Problem

Given a graph G , find a maximum matching of G .

Definition: Maximum Matching ILP

$$\begin{aligned} \max \quad & \sum (x_e : e \in E) \\ \text{s.t.} \quad & x(\delta(v)) \leq 1, \forall v \in V \\ & x_e \geq 0, \forall e \in E \\ & x_e \text{ integer}, \forall e \in E \end{aligned}$$

Definition: Maximum Matching LP Relaxation

$$\begin{aligned} \max \quad & \sum (x_e : e \in E) \\ \text{s.t.} \quad & x(\delta(v)) \leq 1, \forall v \in V \\ & x_e \geq 0, \forall e \in E \end{aligned}$$

Definition: Minimum Cover Dual LP

$$\begin{aligned} \min \quad & \sum (y_v : v \in V) \\ \text{s.t.} \quad & y_u + y_v \geq 1, \forall e = (u, v) \in E \\ & y_v \geq 0, \forall v \in V \end{aligned}$$

Let M be a matching and C be a cover, then

$$x_e^M = \begin{cases} 1 & \text{if } e \in M \\ 0 & \text{if } e \notin M \end{cases}, y_v^C = \begin{cases} 1 & \text{if } v \in C \\ 0 & \text{if } v \notin C \end{cases}$$

So, $\nu(G) \leq \nu^*(G)$ and $\tau(G) \geq \tau^*(G)$, and by LP duality, we have

$$\nu(G) \leq \nu^*(G) = \tau^*(G) \leq \tau(G)$$

9.6 Perfect Matching

9.6.1 Blossom Algorithm for Perfect Matching

Suppose we have a matching M of G and a fixed M -exposed vertex r of G . We can iteratively build up sets A, B of vertices such that each vertex in A is the other end of an odd-length M -alternating path beginning at r , and each vertex in B is the other end of an even-length M -alternating path beginning at r .

Begin with $A = \emptyset, B = \{r\}$, and use the rule: if $vw \in E, v \in B, w \notin A \cup B, wz \in M$, then add w to A , z to B . The set $A \cup B$ and edges in the construction form a tree T rooted at r .

Definition: M -Alternating Tree

A tree T such that

- every vertex of T other than r is covered by an edge of $M \cap E(T)$;
- for every vertex v of T , the path in T from v to r is M -alternating.

We let the vertex sets at odd and even distances from the root as $A(T)$ and $B(T)$ respectively. Note that $|B(T)| = |A(T)| + 1$ since all other vertices other than r come in matched pairs, one in $A(T)$ and one in $B(T)$.

Algorithm Sketch: Given a matching M , if M is not perfect, search for an augmenting path P . Recall that $M' = M \Delta E(P)$ gives us a larger matching since $|M'| = |M| + 1$.

If the algorithm does not find an augmenting path, then we need to certify that G has no perfect matching. We can use Tutte's Matching Theorem to find a Tutte set A where $oc(G \setminus A) > |A|$.

Let $r \in V$ be M -exposed. Grow an M -alternating tree T .

Choose an edge $vw \in E$ with $v \in B(T)$ and $w \notin A(T)$.

Case 1: w is M -exposed.

We have an augmenting path from r to w , so we can augment this path to get a larger matching. We reset T since r is now M -covered.

Case 2: $w \notin V(T)$ and w is M -covered.

We can grow T by adding vw and the edge $e \in M$ having w as an end.

Case 3: $w \in B(T)$.

Let C be the circuit formed from vw and the path in T joining v and w . $|C|$ is odd since vertices in $B(T)$ are at even distances from r .

Note: $|M \cap E(C)| = \frac{|C|-1}{2}$ so M is a near-perfect matching of C .

Definition: Blossom

Let $v, w \in B(T)$ and $vw \in E(G)$. The odd circuit in $T + vw$ is a blossom.

Definition: Shrink

Let C be an odd circuit in G . Define $G' = G \times C$ as the subgraph obtained from G by shrinking C ; G' has vertex set $(V - V(C)) \cup \{C\}$ and edge set $E \setminus \gamma(V(C))$.

Definition: Pseudonode

The vertex after shrinking a blossom.

Let $G' \times C$ denote the graph obtained by shrinking C . The near-perfect matching allows us to un-shrink an augmenting path. Note that the pseudonode is in $B(T)$.

Definition: Frustrated

An M -alternating tree T in a graph G is frustrated if every edge of G has one end in $B(T)$ and the other end in $A(T)$.

Definition: $S(v)$

Given a vertex v of G' , there corresponds a set $S(v)$ of vertices of G , where

$$S(v) = \begin{cases} v & \text{if } v \in V(G) \\ \bigcup_{w \in V(C)} S(w) & \text{if } v = C \text{ is a pseudonode} \end{cases}$$

Lemma

Let M' be a matching of G' and let T be an M' -alternating tree of G' such that no element of $A(T)$ is a pseudonode. If T is frustrated, then G has no perfect matching.

Proof. When we delete $A(T)$ from G' , we get a component with vertex set $S(v)$ for each $v \in B(T)$. By construction, $|S(v)|$ is odd since it is the union of an odd number of vertices and pseudonodes u each having $|S(u)|$ odd. Since $|B(T)| = |A(T)| + 1$, then $oc(G \setminus A(T)) > |A(T)|$. $A(T)$ is therefore a Tutte set. \square

Algorithm 4 Blossom Algorithm (Perfect Matching)

- 1: **Input:** Graph G and matching M of G
 - 2: Choose an M -exposed vertex r
 - 3: $T = (\{r\}, \emptyset)$
 - 4: **while** there exists $vw \in E$ with $v \in B(T), w \notin A(T)$ **do**
 - 5: **Case:** w is M' -exposed
 - 6: Let P be the augmenting path from r to w , $M = M \Delta E(P)$
 - 7: **if** there is no M -exposed vertex in G **then**
 - 8: **return** Perfect matching M
 - 9: **else**
 - 10: $T = (\{r\}, \emptyset)$, where r is M -exposed
 - 11: **Case:** $w \notin V(T)$, w is M -covered
 - 12: Let $wz \in M$ and $z \notin V(T)$, $E(T) = E(T) \cup \{vw, wz\}$
 - 13: **Case:** $w \in B(T)$
 - 14: Let C be the circuit formed from vw and the vw -path in T
 - 15: $G = G \times C$ // Shrink C
 - 16: **return** G has no perfect matching, $A(T)$ is the Tutte set
-

Theorem

The Blossom Algorithm terminates after $O(n)$ augmentations, $O(n^2)$ shrinking steps, and $O(n^2)$ tree-extension steps.

Moreover, it determines correctly whether G has a perfect matching.

9.7 Blossom Algorithm for Maximum Matching

We can extend the Blossom algorithm for perfect matchings to maximum matchings.

Algorithm 5 Blossom Algorithm (Maximum Matching)

```

1: Input: Graph  $G$  and matching  $M$  of  $G$ 
2:  $\mathcal{T} = \emptyset$ 
3: Choose an  $M$ -exposed vertex  $r$ 
4:  $T = (\{r\}, \emptyset)$ 
5: while there exists  $vw \in E$  with  $v \in B(T), w \notin A(T)$  do
6:   Case:  $w$  is  $M$ -exposed
7:     Let  $P$  be the augmenting path from  $r$  to  $w$ ,  $M = M \Delta E(P)$ 
8:     if there is no  $M$ -exposed vertex then
9:       return Perfect matching  $M$ 
10:    else
11:       $T = (\{r\}, \emptyset)$ , where  $r$  is  $M$ -exposed
12:    Case:  $w \notin V(T)$ ,  $w$  is  $M$ -covered
13:      Let  $wz \in M$  and  $z \notin V(T)$ ,  $E(T) = E(T) \cup \{vw, wz\}$ 
14:    Case:  $w \in B(T)$ 
15:      Let  $C$  be the circuit formed from  $vw$  and the  $vw$ -path in  $T$ 
16:       $G = G \times C$  // Shrink  $C$ 
17:  $\mathcal{T} = \mathcal{T} \cup \{T\}, G = G \setminus V(T), M = M \setminus E(T)$ 
18: if there exists an  $M$ -exposed vertex then
19:   Go to line 5
20: Restore the matching  $M$ 
21: return  $M$ 

```

Theorem

The Blossom Algorithm can be implemented to run in time $O(nm \log n)$.

Chapter 10

Weighted Matching

10.1 Minimum-Cost Perfect Matching

10.1.1 Perfect Matching Polytope

By Minkowski's theorem, we know that there is a system of inequalities for the convex hull of a set, but we typically do not know what the system is. However, Edmonds founded the matching polytope theory in the 1960s.

The integer program for the minimum-cost perfect matching problem is

$$\begin{aligned} \min \quad & \sum (c_e x_e : e \in E) \\ \text{s.t.} \quad & x(\delta(v)) = 1, \forall v \in V \\ & x_e \geq 0, \forall e \in E \\ & x_e \text{ integer}, \forall e \in E \end{aligned}$$

If G is bipartite, then we do not need the integrality constraint. If G is non-bipartite, then there exists a circuit C with $|E(C)|$ odd.

For a general graph, the original minimum-weight perfect matching LP can achieve an optimal solution, which may be a fractional vertex of the polyhedron defined by the LP. This is caused by the odd circuits in the graph.

Definition: Perfect Matching Polytope

$$\mathcal{PM}(G) = \text{conv.hull}(\{x^M : M \text{ a perfect matching}\})$$

Edmonds' Perfect Matching Polytope Theorem

Let $S \subseteq V$ with $|S|$ odd and $|S| \geq 3$. For an undirected graph, every perfect matching must contain at least one edge in $\delta(S)$, so we arrive at the blossom inequality constraint.

Definition: Blossom Inequality

For $S \subseteq V$ with $|S|$ odd and $|S| \geq 3$,

$$x(\delta(S)) \geq 1$$

Theorem (Perfect Matching Polytope Theorem – Edmonds)

For any graph $G = (V, E)$, $\mathcal{PM}(G)$ is the solution set of the linear system

$$\begin{aligned} x(\delta(v)) &= 1, \quad \forall v \in V \\ x(\delta(S)) &\geq 1, \quad \forall S \subseteq V, |S| \text{ odd}, |S| \geq 3 \\ x_e &\geq 0, \quad \forall e \in E \end{aligned}$$

Proof. (Schrijver) Let Q denote the solution set of the linear system. Clearly $\mathcal{PM}(G) \subseteq Q$. Suppose $Q \not\subseteq \mathcal{PM}(G)$ and let x be a vertex of Q with $x \notin \mathcal{PM}(G)$. Choose this counterexample G such that $|V| + |E|$ is as small as possible.

Claim 1: $0 < x_e < 1$ for all $e \in E$.

Proof. (Claim 1) Otherwise, if $x_e = 0$, then delete e . If $x_e = 1$, then delete e and the ends of e . \square

So each vertex of G has degree at least 2, which implies $|E| \geq |V|$.

Claim 2: $|E| > |V|$.

Proof. (Claim 2) If $|E| = |V|$, then G is a circuit and the theorem is true. \square

Since x is a vertex of Q , there are $|E|$ constraints of the linear system satisfied as an equation by x . Thus, there exists an odd $S \subseteq V$ with $3 \leq |S| \leq |V| - 3$ and $x(\delta(S)) = 1$.

Let G' be the graph obtained by shrinking S to a single vertex and G'' be obtained by shrinking $V \setminus S$ to a single vertex. Let x' and x'' be obtained by shrinking x to G' and G'' respectively. So x' and x'' satisfy the linear system for G' and G'' . By induction, $x' \in \mathcal{PM}(G')$ and $x'' \in \mathcal{PM}(G'')$.

Since x is rational, x' and x'' are rational convex combinations of perfect matchings in G' and G'' , i.e.

$$x' = \frac{1}{k} \sum_{i=1}^k x^{M'_i}, x'' = \frac{1}{k} \sum_{i=1}^k x^{M''_i}$$

for some k (the common denominator of the multipliers λ'_i and λ''_i in the convex combinations).

For each edge $e \in \delta(S)$, the number of indices i with $e \in M'_i$ is $kx'_e = kx_e = kx''_e$ which is equal to the number of indices i with $e \in M''_i$.

We may assume that for each i , the two matchings M'_i and M''_i have an edge in $\delta(S)$ in

common. So $M_i = M'_i \cup M''_i$ is a perfect matching of G and

$$x = \frac{1}{k} \sum_{i=1}^k x^{M_i}$$

and thus $x \in \mathcal{PM}(G)$, a contradiction. \square

10.1.2 Linear Programming

Definition: ODD

$$\text{ODD} = \{S \subseteq V : |S| \text{ odd}, |S| \geq 3, |S| \leq |V| - 3\}$$

Definition: Minimum-Cost Perfect Matching LP

$$\begin{aligned} \min \quad & \sum (c_e x_e : e \in E) \\ \text{s.t.} \quad & x(\delta(v)) = 1, \forall v \in V \\ & x(\delta(S)) \geq 1, \forall S \in \text{ODD} \\ & x_e \geq 0, \forall e \in E \end{aligned}$$

Definition: Minimum-Cost Perfect Matching Dual LP

$$\begin{aligned} \max \quad & \sum (y_v : v \in V) + \sum (Y_S : S \in \text{ODD}) \\ \text{s.t.} \quad & y_v + y_w + \sum (Y_S : e \in \delta(S), S \in \text{ODD}) \leq c_e, \forall e = vw \in E \\ & Y_U \geq 0, \forall S \in \text{ODD} \end{aligned}$$

Definition: Reduced Cost

Given a dual solution (y, Y) , the reduced cost of an edge $e = vw$ is

$$\bar{c}_e = c_e - y_v - y_w - \sum (Y_S : e \in \delta(S), S \in \text{ODD})$$

Definition: Complementary Slackness Conditions

Let $x = (x_e : e \in E)$, $y = (y_v : v \in V)$, $Y = (Y_S : S \in \text{ODD})$.

- (i) If $x_e > 0$, then $\bar{c}_e = 0$.
- (ii) If $Y_S > 0$, then $x(\delta(S)) = 1$.

In other words, we only want edges having reduced cost 0 and only use dual variables Y_S if $\delta(S)$ contains exactly one matching edge.

10.1.3 Blossom Algorithm

Definition: Equality Subgraph $E^=$

$$E^= = \{e \in E : \bar{c}_e = 0\}$$

We need a perfect matching in $E^=$ such that if $Y_S \geq 0$, then $|\delta(S) \cap M| = 1$.

Algorithm Sketch: Grow an alternating tree using only $E^=$ edges, starting at an M -exposed vertex. Unlike the unweighted algorithm, we need to keep the shrunk graph from iteration to iteration, because of the CS conditions on the Y_S variables. Similar to the unweighted version, we choose an edge $e = vw$ with $v \in B(T), w \notin A(T)$. If none exist, we will possibly change the dual solution to create new edges in $E^=$.

Algorithm 6 Blossom Algorithm (Minimum-Cost Perfect Matching)

```
1: Input: Graph  $G$ 
2:  $M = \emptyset, Y_S = 0 : \forall S \in \text{ODD}, y_v = 0 : \forall v \in V$ 
3:  $T = (\{r\}, \emptyset)$ , where  $r$  is an  $M$ -exposed vertex
4: while true do
5:   Case:  $e = vw \in E^-$  with  $v \in B(T), w \notin A(T)$ 
6:     Case:  $w$  is  $M$ -exposed
7:       Let  $P$  be the augmenting path from  $r$  to  $w$ ,  $M = M \Delta E(P)$ 
8:       if there is no  $M$ -exposed vertex then
9:         return Perfect matching  $M$ 
10:      else
11:         $T = (\{r\}, \emptyset)$ , where  $r$  is  $M$ -exposed.
12:      Case:  $w \notin V(T)$ ,  $w$  is  $M$ -covered
13:        Let  $wz \in M$  and  $z \notin V(T)$ ,  $E(T) = E(T) \cup \{vw, wz\}$ 
14:      Case:  $w \in B(T)$ 
15:        Let  $C$  be the circuit formed from  $vw$  and the  $vw$ -path in  $T$ 
16:         $G = G \times C$  // Shrink  $C$ 
17:      Case: No edge  $e = vw$  available
18:         $\varepsilon_1 = \min(\bar{c}_e : e \text{ joins a vertex in } B(T) \text{ to a vertex not in } V(T))$  // next iteration
        will augment  $M$  or grow  $T$ 
19:         $\varepsilon_2 = \min(\bar{c}_e/2 : e \text{ joins two vertices in } B(T))$  // next iteration will shrink the odd
        circuit
20:         $\varepsilon_3 = \min(y_v : v \in A(T), v \text{ a pseudonode})$ 
21:         $\varepsilon = \min(\varepsilon_1, \varepsilon_2, \varepsilon_3)$ 
22:        if  $\varepsilon = \infty$  then
23:          return  $G$  has no perfect matching; there exists a Tutte set
24:         $y_v = y_v + \varepsilon$  if  $v \in B(T)$  //  $y_v$  may be a pseudonode, so  $y_v$  is actually  $Y_S$ 
25:         $y_v = y_v - \varepsilon$  if  $v \in A(T)$  //  $y_v$  may be a pseudonode, so  $y_v$  is actually  $Y_S$ 
26:        if  $\varepsilon = \varepsilon_3$  then
27:          Unshrink the pseudonode  $v \in A(T)$  that attained the minimum
28:          Let  $s, t$  be the vertices adjacent to  $v$ 
29:          Keep the even-length  $st$ -path in  $T$ 
```

The Blossom Algorithm for Minimum-Cost Perfect Matching above has runtime complexity $O(mn^2)$. This can be improved to $O(n^3)$.

10.2 Maximum-Weight Matching

Definition: Odd-Cut

The set $\delta(S)$ where $|S|$ is odd.

Perfect Matching Separation Problem

Given $x = (x_e : e \in E)$, find an odd-set S such that $x(\delta(S)) < 1$ if such a set exists.

First we set $\bar{x}_e = w_e$ for all $e \in E$. We find a minimum-weight cut in G , i.e. $\min \sum (w_e : e \in \delta(S))$ over all proper subsets $S \subseteq V$. This can be done by solving $n - 1$ max-flow min-cut problems (or other methods).

If $|S|$ is odd, then $\delta(S)$ is a minimum-weight odd-cut in G . We check if the weight < 1 . If yes, then it is a separating inequality. If no, then no separating inequality exists.

If $|S|$ is even, show there exists a minimum-weight odd-cut $\delta(U)$ with $U \subseteq S$ or $U \subseteq V \setminus S$. We can solve the problem on two smaller by having two graphs, one shrinking S and the other shrinking $V \setminus S$. We call the shrunk vertex even and original vertices odd. Thus, we look for U with an odd number of odd vertices. This gives a polynomial time algorithm, but it is not efficient for large graphs. Faster algorithms use Gomory-Hu trees (Padberg & Rao).

10.2.1 Matching Polytope

Definition: Matching Polytope

$$\mathcal{M}(G) = \text{conv.hull}(\{x^M : M \text{ a matching}\})$$

Consider the maximum-weight matching LP,

$$\begin{aligned} \max \quad & \sum (c_e x_e : e \in E) \\ \text{s.t.} \quad & x(\delta(v)) \leq 1, \forall v \in V \\ & x_e \geq 0, \forall e \in E \end{aligned}$$

If we had a triangle graph with $c_e = 1$ for all $e \in E$, then we can get an optimal solution of $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ with value $\frac{3}{2}$, but the optimal matching is only 1 with one edge. So we need to add inequalities.

Definition: $\gamma(S)$

For $S \subseteq V$,

$$\gamma(S) = \{vw : vw \in E, v \in S, w \in S\}$$

If $|S|$ is odd, every matching x^M satisfies $x(\delta(S)) \leq \frac{|S|-1}{2}$. This is the blossom inequality for matchings.

Note that

$$x(\delta(S)) = \frac{1}{2} \sum (x(\delta(v)) : v \in S) - x(\delta(S))$$

Thus, for perfect matchings, we have

$$\begin{aligned}
x(\delta(S)) \geq 1 &\iff -x(\gamma(S)) + \frac{1}{2} \sum (x(\delta(v)) : v \in S) \geq 1 \\
&\iff -x(\gamma(S)) + \frac{1}{2} |S| \geq 1 \\
&\iff x(\gamma(S)) \leq \frac{1}{2} |S| - 1 = \frac{|S| - 1}{2}
\end{aligned}$$

So for perfect matchings, the two forms of the blossom inequality are equivalent.

Definition: Blossom Inequality

For $S \subseteq V$ with $|S|$ odd and $|S| \geq 3$,

$$x(\gamma(S)) \leq \frac{|S| - 1}{2}$$

Theorem (Edmonds)

$\mathcal{M}(G)$ is defined by

$$\begin{aligned}
x(\delta(v)) &\leq 1, \quad \forall v \in V \\
x(\gamma(S)) &\leq \frac{|S| - 1}{2}, \quad \forall S \in \text{ODD} \\
x_e &\geq 0, \quad \forall e \in E
\end{aligned}$$

Proof. *Sketch* (Schrijver) Let Q be the solution set of the inequality system. We have $\mathcal{M}(G) \subseteq Q$.

Let $x \in Q$. We must show $x \in \mathcal{M}(G)$. Let G' be a copy of the graph G . Form a graph $\tilde{G} = G \cup G'$ with additional edges (v, v') for all $v \in V$. Set $\tilde{x}_e = \tilde{x}_{e'} = x_e$ for all $e \in E$ and $\tilde{x}_{vv'} = 1 - x(\delta(v))$ for all $v \in V$.

Claim: $\tilde{x} \in \mathcal{PM}(\tilde{G})$.

The idea of the proof is to show \tilde{x} satisfies each blossom constraint (the \leq form). Then the claim implies $x \in \mathcal{M}(G)$. \square

The dual LP of the maximum-weight matching is

$$\begin{aligned}
\min \quad & \sum (y_v : v \in V) + \sum \left(\left(\frac{|S| - 1}{2} \right) Y_S : S \in \text{ODD} \right) \\
\text{s.t.} \quad & y_v + y_w + \sum (Y_S : e \in \gamma(S), S \in \text{ODD}) \geq c_e \\
& y_v \geq 0, \quad \forall v \in V \\
& Y_S \geq 0, \quad \forall S \in \text{ODD}
\end{aligned}$$

Recall that in the Blossom algorithm, the ε used in the dual change includes $\varepsilon_1, \varepsilon_2, \varepsilon_3$. ε_2 may introduce fractional values for the dual variables, even when c_e is integer for all $e \in E$.

If c_e is integer for all $e \in E$, then the Blossom algorithm will return a dual solution (y, Y) such that Y is integer and y is $\frac{1}{2}$ -integer.

Theorem (Cunningham & Marsh 1978)

For the matching LP, if $(c_e : e \in E)$ are integers, then there exists an optimal dual solution (y, Y) that is integer.

This theorem says the blossom system for matchings is TDI.

Chapter 11

General Matching

By a sequence of reductions, Edmonds' results can be extended to a general matching setting. For a graph $G = (V, E)$, let M be a $|V| \times |E|$ matrix such that all entries are $0, \pm 1, \pm 2$ and the sum of absolute values of entries in each column is at most 2.

For the problem

$$\begin{aligned} \max \quad & \sum (w_e x_e : e \in E) \\ \text{s.t.} \quad & b_1 \leq Mx \leq b_2 \\ & c_1 \leq x \leq c_2 \\ & x_e \text{ integer, } \forall e \in E \end{aligned}$$

Edmonds and Johnson described the polyhedron and an algorithm.

Definition: 2-Factor

A set $F \subseteq E$ such that every $v \in V$ meets exactly 2 edges in F .

A 2-factor is a set of disjoint circuits covering all vertices. 2-factors are a relaxation of the TSP. In TSP, we want a single circuit covering all vertices.

$$\begin{aligned} x(\delta(v)) &= 2, \forall v \in V \\ 0 &\leq x_e \leq 1, \forall e \in E \\ x_e &\text{ integer, } \forall e \in E \end{aligned}$$

To describe the 2-factor polytope, we need a version of the blossom inequalities.

Definition: Blossom Inequality for 2-Factors

Let $U \subseteq V, F \subseteq \delta(U)$ where F is a matching and $|F|$ is odd, then every 2-factor satisfies

$$x(\delta(U) \setminus F) - x(F) \geq 1 - |F|$$

Adding all of these inequalities gives the convex hull of 2-factors.

Chapter 12

T -Joins

Definition: T -Join

Let $G = (V, E)$ be a graph and $T \subseteq V$ with $|T|$ even. A T -join is a set $J \subseteq E$ such that

$$|J \cap \delta(v)| \text{ is odd} \iff v \in T$$

In other words, J is a T -join if and only if the odd-degree vertices of the subgraph (V, J) are exactly the elements of T .

Optimal T -Join Problem

Given a graph $G = (V, E)$, a set $T \subseteq V$ such that $|T|$ is even, and a cost vector $c \in \mathbb{R}^E$, find a T -join J of G such that $c(J)$ is minimum.

Every T -join is the edge-disjoint union of circuits and $\frac{1}{2}|T|$ paths connecting pairs of vertices in T .

If $c_e \geq 0$ for all $e \in E$, then there exists an optimal T -join that consists of $\frac{1}{2}|T|$ paths connected pairs in T .

Special cases:

- Perfect matchings, let $T = V$.
- rs -shortest path, let $T = \{r, s\}$.

12.1 Chinese Postman Problem

A main motivation is the Chinese Postman Problem.

Chinese Postman Problem (CPP)

Given a connected graph $G = (V, E)$, edge costs $(c_e : e \in E), c_e \geq 0, \forall e \in E$, find a minimum-cost closed path that uses each of G at least once.

Definition: Euler Tour

A closed edge-simple path P with $E(P) = E(G)$.

Theorem

A connected graph G has an Euler tour if and only if every vertex of G has even degree.

If G has an Euler tour T , then T is an optimal solution to the CPP. If G does not have an Euler tour, then we must use some edges more than once. By the above theorem, we never need to use any edge more than twice.

Thus, to solve the CPP, we want to find a minimum-cost set of edges $J \subseteq E$ such that duplicating every edge in J gives a graph with every vertex of even degree.

12.2 Optimal T -Join Algorithm

To solve the CPP, we let $T = \{v \in V : \deg(v) \text{ odd}\}$. Edmonds gives a polynomial time algorithm by reducing the problem to a perfect matching.

We can assume $c_e \geq 0$ for all $e \in E$. To see this, let $N = \{e : c_e < 0\}$ and let $U = \{v : v \text{ has odd degree in } (V, N)\}$, $T' = T \Delta U$ and $c'_e = |c_e|$ for all $e \in E$. Now let J' be a minimum c' -weight T' -join.

Claim: $J = J' \Delta N$ is a minimum c -weight T -join.

We can now reduce the problem to a perfect matching problem (Edmonds). Consider the complete graph K_T with vertex set T . For each edge $uv \in E(K_T)$, let ℓ_{uv} be the length of a shortest uv -path in G and let P_{uv} denote the path.

Using ℓ_{uv} as edge costs, find a minimum-cost perfect matching in K_T . Let M denote the optimal matching. Then the symmetric difference of the paths P_{uv} for all $uv \in M$ (keep the edges that appear an odd number of times in the collection) is a minimum-cost T -join.

Notes:

1. By setting $T = \emptyset$, we get a polynomial time algorithm to check for a negative-cost circuit in G .
2. If no negative-cost circuit, setting $T = \{r, s\}$, we get a polynomial time rs -path algorithm for undirected graphs.

3. We get a polynomial time algorithm for the CPP.

Algorithm 7 Optimal T -Join Algorithm

- 1: Let $N = \{e : c_e < 0\}$ and $U = \{v : v \text{ has odd degree in } (V, N)\}$
 - 2: $c = |c|, T = T \Delta U$
 - 3: Let K_T be the complete graph on vertex set T
 - 4: For each $uv \in E(K_T)$, give uv edge cost $\ell_{uv} = \text{cost of shortest } uv\text{-path in } G$
 - 5: Find a minimum-weight perfect matching M in K_T
 - 6: Let J be the symmetric difference of $E(P_{uv})$ for $uv \in M$ (keep edges that appear an odd number of times)
 - 7: $J = J \Delta N$
 - 8: **return** J
-

12.3 Linear Programming

Definition: T -Odd

A set $S \subseteq V$ is T -odd if $|S \cap T|$ is odd.

If $J \subseteq E$ is a T -join, then we must have $J \cap \delta(S) \neq \emptyset$ if S is T -odd.

Definition: T -Cut

The set $\delta(S)$ where $S \subseteq V$ is T -odd.

For a T -cut $\delta(S)$, every T -join satisfies $x(\delta(S)) \geq 1$.

Definition: T -Join LP

$$\begin{aligned} \min \quad & \sum (c_e x_e : e \in E) \\ \text{s.t.} \quad & x(D) \geq 1, \forall T\text{-cuts } D \\ & x_e \geq 0, \forall e \in E \end{aligned}$$

If $c_e < 0$ for some $e \in E$ and G has a T -join, then the LP is unbounded.

Theorem (Edmonds & Johnson)

If $c_e \geq 0$ for all $e \in E$, then the minimum cost of a T -join is equal to the optimal value of the T -join LP.

Geometry: If $P = \text{conv.hull}(\{x^J : J \text{ a } T\text{-join}\})$, then the polyhedron defined by

$$\begin{aligned} x(D) &\geq 1, \forall T\text{-cuts } D \\ x &\geq 0 \end{aligned}$$

is $P + \mathbb{R}_+^n$ is the **dominant** of P , i.e. everything above P .

Definition: T -Join Dual LP

$$\begin{aligned} \max \quad & \sum (y_D : D \text{ a } T\text{-cut}) \\ \text{s.t.} \quad & \sum (y_D : e \in D, D \text{ a } T\text{-cut}) \leq c_e, \forall e \in E \\ & y_D \geq 0, \forall T\text{-cuts } D \end{aligned}$$

If $c_e = 1$ for all $e \in E$, then an integer dual solution gives a collection of edge-disjoint T -cuts, called a **packing** of T -cuts.

Research problem: For which (G, T) is the minimum cardinality of a T -join equal to the maximum packing of T -cuts? This is true if G is bipartite. Abdi and Guenin has results when $|T| \leq 4$.

Notes:

1. If J is a T -join and D is a T -cut, then $J \cap D \neq \emptyset$.
2. If $C \subseteq E$ is such that $C \cap J \neq \emptyset$ for all T -joins J , then C contains a T -cut.

Proof. Consider the graph $G' = (V, E \setminus C)$. Each connected component of G' has an even number of vertices in T . So there is a T -join disjoint from C . \square

3. Minimal T -cuts are exactly the minimal edge sets that intersect all T -joins.
4. Minimal T -joins are exactly the edge sets that intersect all T -cuts.

12.4 Clutters

Definition: Clutter

A family of subsets \mathcal{C} is called a clutter if for all $A, B \in \mathcal{C}$, we have $A \not\subseteq B$ and $B \not\subseteq A$.

Packing problem: Find the maximum number of disjoint members of \mathcal{C} .

Definition: Blocker

The blocker of \mathcal{C} is the family of minimal sets that intersect all members of \mathcal{C} .

Theorem (Edmonds & Fulkerson)

$\text{blocker}(\text{blocker}(e)) = e$.

Part VI

Matroids

Chapter 13

Matroid Theory

Matrix Example: Let A be a matrix in $\mathbb{R}^{m \times n}$ and let E be the column indices of A . We call $I \subseteq E$ independent if the column vectors of I are linearly independent in \mathbb{R}^m .

- (0) \emptyset is independent.
- (1) If I is independent, then so is any subset of I .
- (2) For any $X \subseteq E$, any two maximal independent sets in X have the same size. The size is equal to the column rank of $(A_e : e \in X)$.

A standard proof of (2) is for $X \subseteq E$,

- (i) $I \subseteq X$ is independent, then $|I| \leq \text{rank}(X)$.
- (ii) $I \subseteq X$ is independent and $|I| < \text{rank}(X)$, then there exists a column index $e \in X \setminus I$ such that $I \cup \{e\}$ is independent.

Graph Example: Let $G = (V, E)$ be a graph. Call $I \subseteq E$ independent if it contains no circuit.

- (0) \emptyset is independent.
- (1) If I is independent, then so is any subset of I .
Note that I is independent if it induces a forest. So any independent set has size at most $|V| - \kappa(G)$.
- (2) For any $X \subseteq E$, any two maximal independent sets in X have the same size.

13.1 Matroids

Definition: Matroid

Let E be a finite set (*ground set*) and \mathcal{I} be a family of subsets of E (*independent sets*). A matroid M is a pair (E, \mathcal{I}) such that

- (M0) $\emptyset \in \mathcal{I}$ (\emptyset is independent).
- (M1) If $J' \subseteq J \in \mathcal{I}$, then $J' \in \mathcal{I}$.
- (M2) For all $X \subseteq E$, every maximal independent subset contained in X has the same cardinality.

Definition: Rank

The constant size in (M2) is called the rank of X , denoted by $r(X)$.

Definition: Basis

An independent set of size $r(E)$ is called a basis of M .

Definition: Dependent

A subset that is not independent.

Definition: Circuit

A minimal dependent set.

Waterloo is a center for matroid research. Tutte built the field. Matroid optimization was developed by Edmonds. Cunningham worked on matroid structure.

Matroid Optimization Problem

Let $M = (E, \mathcal{I})$ be a matroid and $c = (c_e : e \in E)$. Find a maximum-weight independent set $I \in \mathcal{I}$.

Algorithm 8 Greedy Algorithm

- 1: $J = \emptyset$
 - 2: **while** there exists $e \in E \setminus J$ with $c_e > 0$ and $J \cup \{e\} \in \mathcal{I}$ **do**
 - 3: Choose e with c_e maximum
 - 4: $J = J \cup \{e\}$
 - 5: **return** J
-

Theorem

For any matroid M , the greedy algorithm produces a maximum-weight independent set.

Proof. Suppose not. Let $J \in \mathcal{I}$ be a set produced by greedy and let $J' \in \mathcal{I}$ be such that $c(J') > c(J)$.

Let $J = \{e_1, \dots, e_r\}$ where the elements are chosen by greedy in the order e_1, \dots, e_r . Note that $c_{e_1} \geq \dots \geq c_{e_r}$. Let $J' = \{f_1, \dots, f_\ell\}$ where $c_{f_1} \geq \dots \geq c_{f_\ell}$.

Let k be the smallest index such that $c_{f_k} > c_{e_k}$. If none exist, then $\ell > m$ and in this case set $k = m + 1$.

In step k , the greedy algorithm did not add one of f_1, \dots, f_k . Now since $c_{e_k} < c_{f_k}$, we have

$$\begin{aligned} \{e_1, \dots, e_{k-1}\} \cup \{f_1\} &\notin \mathcal{I} \text{ or } f_1 \in \{e_1, \dots, e_{k-1}\} \\ \{e_1, \dots, e_{k-1}\} \cup \{f_2\} &\notin \mathcal{I} \text{ or } f_2 \in \{e_1, \dots, e_{k-1}\} \\ &\vdots \\ \{e_1, \dots, e_{k-1}\} \cup \{f_k\} &\notin \mathcal{I} \text{ or } f_k \in \{e_1, \dots, e_{k-1}\} \end{aligned}$$

Thus, $\{e_1, \dots, e_{k-1}\}$ is a maximal independent set in

$$X = \{e_1, \dots, e_{k-1}\} \cup \{f_1, \dots, f_k\}$$

So, by (M2), every independent set in X has size at most $k - 1$. But J' has size k , a contradiction. \square

Definition: Independence System

(E, \mathcal{I}) satisfying (M0) and (M1).

Theorem

An independence system is a matroid if and only if for all $c = (c_e : e \in E)$, the greedy algorithm finds a maximum weight independent set.

Proof. If (E, \mathcal{I}) is not a matroid, let X be a set that violates (M2). Let

$$c_e = \begin{cases} 1 & \text{if } e \in X \\ 0 & \text{if } e \notin X \end{cases}$$

There exists a maximal independent set $I \subseteq X$ that is not of maximum cardinality. But I could potentially be a solution produced by the greedy algorithm. \square

Proposition (Submodularity)

Let $M = (E, \mathcal{I})$ be a matroid with rank function r . Then for all $X, Y \subseteq E$, we have

$$r(X) + r(Y) \geq r(X \cap Y) + r(X \cup Y)$$

Proof. Choose $A \subseteq X \cap Y, B \subseteq X \setminus Y, C \subseteq Y \setminus X$ as follows.

- A is a maximal independent set in $X \cap Y$.

- $A \cup B$ is a maximal independent set in X .
- $A \cup B \cup C$ is a maximal independent set in $X \cup Y$.

Then,

$$\begin{aligned}
r(X \cap Y) + r(X \cup Y) &= |A| + |A \cup B \cup C| \\
&= (|A| + |B|) + (|A| + |C|) \\
&= r(X) + (|A| + |C|) \\
&\leq r(X) + r(Y)
\end{aligned}$$

□

13.2 Examples of Matroids

Uniform Matroid: Let E be a finite set with $|E| = n$ and choose an integer $k \in \{0, \dots, n\}$. Call a subset E independent if it has size at most k and let \mathcal{I} be the collection of all independent sets.

Let $U_n^k = (E, \mathcal{I})$, then U_n^k is a matroid. **Proof.** (M0) and (M1) hold. For any $X \subseteq E$, any maximal independent set contained in X has size $\min(k, |X|) = r(X)$. □

Partition Matroid: Let E be a finite set and let E_1, \dots, E_k be a partition of E . Call $I \subseteq E$ independent if I picks at most one element from each partition. That is, for $i = 1, \dots, k$, we have $|I \cap E_i| \leq 1$. Let \mathcal{I} be the collection of all independent sets. Then (E, \mathcal{I}) is a matroid.

Proof. $M = (E, \mathcal{I})$ is a matroid. (M0) and (M1) hold. Suppose $X \subseteq E$. Any maximal independent set in X has size $|\{i : X \cap E_i \neq \emptyset\}| = r(X)$. □

13.3 Maximum-Weight Basis

If $c_e > 0$ for all $e \in E$, then a maximum-weight independent set is a basis.

If some of the weights are negative, this may not be the case.

To find a maximum-weight independent basis, modify the greedy algorithm to accept negative-cost elements. Alternatively, we could add a large constant Δ to all c_e .

Part VII

Traveling Salesman Problem

Chapter 14

The Traveling Salesman Problem

Definition: Tour

A circuit that passes exactly once through each vertex.

This is also known as a Hamiltonian circuit.

Traveling Salesman Problem (TSP)

Given a finite set of points V and a cost c_{uv} of travel between each pair $u, v \in V$, find a tour of minimal cost.

The TSP can be modeled as a graph problem by considering the complete graph. TSP belongs to class of \mathcal{NP} -hard problems.
